Change Blindness

Robert W Kentridge, Durham University, Durham, UK

Abstract

Change blindness is a phenomenon in which major changes to a visual scene go unnoticed. There are many methods of inducing change blindness, for example, by presenting a blank image between presentation of the original and changed pictures. Change blindness is thought to occur when visual attention is prevented from being drawn to the change. Detecting the changes requires a comparison between the changed state of the picture and a visual memory of its original state. Without visual attention the memory may not be retrieved at all or the available memory may lack sufficient visual detail for a change to be registered. Change blindness is employed as a tool for studying visual attention and has obvious real-world implications for tasks such as driving.

Overview

If we are looking at a picture and one thing in it changes, someone's hat turns from black to white, we would normally expect to see the change easily. In fact, we would expect the change to jump out at us. There are, however, circumstances where such changes are almost impossible to detect. This is the phenomenon of change blindness. The circumstances in which we fail to detect changes easily all seem to affect visual attention. If, for example, some irrelevant bright spots appear at the same time as the picture changes then we usually fail to detect the change in the picture. Understanding change blindness can help us understand the role of visual attention in perception, and in particular, conscious perception. The mechanisms underlying change blindness are also likely to depend upon the properties of visual short-term memory and the nature of visual representations. Explaining change blindness is therefore of considerable theoretical interest to psychologists. The ability to detect changes in a scene is also of great practical importance. Drivers, for example, need to see a child stepping into the road or a traffic light changing. Understanding how factors in their environment might interfere with these abilities is an example of especially valuable applied psychology.

History and Methods

The discovery of change blindness arose out of research aimed at understanding how the visual system integrates information across eye movements. Although the visual world appears stable to us, we actually move our gaze rapidly from place to place several times per second. These rapid shifts of gaze are known as saccadic eye movements or saccades. The intervening periods during which we keep our gaze fixed on one part of the visual scene are known as fixations. We acquire very little, perhaps no, information during saccades. At each fixation most of the information we do acquire is from a small region of space centered on the direction of fixation. We acquire much less information from the visual periphery as the resolution of visual system decreases markedly away from the direction of gaze. Our sensation of an apparently stable continuous world must be constructed by integrating disjointed patches of vision acquired one after another. One key issue in understanding the integration of information across fixations is the extent to which the relatively poor information acquired from locations in more peripheral vision during one fixation is used to interpret information from subsequent fixations that are made to those locations. Information from the periphery, although not as precise as that obtained from central vision, is certainly used by the visual system in selecting destinations for subsequent saccades. But how much peripheral information is actually used for purposes beyond saccade guidance? Does this peripheral information allow us to match parts of transitory visual representations between fixations in the creation of a global representation of the world?

Early work on integration of information across saccades focused on reading. In this work subjects' direction of gaze was continuously measured with an eye-tracker so that the visual stimulus they were presented with could be manipulated between fixations. Creating such 'gaze-contingent' displays is technically demanding today and was all the more so in the 1970s. At that time it was possible to manipulate a display of text (but not yet a realistic image) so that it changed as a subject moved his or her eyes. This allows one to ask exactly what information is acquired from the periphery on a given fixation. If we can, for example, detect the identity of a letter in the periphery then when we subsequently saccade to it we will notice if the letter has changed. If we are unable to detect letter identity in the periphery then if the letter changes as we saccade to it we will be unaware and will continue reading as normal. One early, and very surprising, result found by McConkie and Zola (1979) was that the visual details of letters could be changed across saccades without being noticed even when changes in the identity of those letters would be detected. If a letter changed from an 'a' to a 'b' the change would be detected, but a change from a lowercase 'a' to an uppercase 'A' would go unseen (in the experiment the text alternated in case, e.g., 'ThE qUiCk BrOwN fOx,' but changed in the order of case alternation across saccades so that a change to 'tHe QuIcK bRoWn FoX,' was undetected). This was all the more remarkable because subjects claimed that they were seeing text in their peripheral vision and that no changes were occurring. This suggests that, in reading at least, our global representation of the world is maintained at quite an abstract level and our

impression of continuous physical detail is 'filled in' without truly being represented or at least explicitly available to us.

A few years later John Grimes (described in Grimes, 1996), working in McConkie's laboratory, began using a system that allowed full color pictures to be switched as a subject made a saccade. Grimes manipulated pictures using Photoshop so that one or two objects in the picture changed. For example, one original picture shows two men, one wearing a black hat and one a gray hat. In the manipulated picture the hats switch colors. If the change between the two images occurs during a saccade subjects very rarely detected the change even though it was glaringly obvious when not synchronized with an eye movement. This failure to detect large changes in a visual scene is an example of what we know known as change blindness.

As the eye-tracker in Grimes' experiments records eye-position as well as controlling the times at which images change it is possible to determine where a subject has been looking during the experiment. Grimes discovered that even when subjects had looked directly at the changing object before it changed, and looked at it again at some time after it changed, they still did not notice the change. Even with information acquired directly from fixation the representation stored in visual short-term memory must either be so abstract that changes in physical detail are unseen or, if physical detail is represented, changes must be integrated without reference to the prior state of the representation.

Grimes' results prompted a number of investigators, most prominently Ronald Rensink and Daniel Simons, to ask why a saccade prevented people from detecting changes in visual scenes. When we make a saccade the visual system partially suppresses sensitivity to visual signals (at least in the part of the visual system sensitive to rapid motion, Burr et al., 1994), a process known as saccadic suppression. What signals that remain are blurred by the motion of the eye. Rensink et al. (1997) asked whether the process of saccadic suppression itself was essential to change blindness or whether just the brief period of motion blur between steadily fixated images was sufficient to prevent changes from being detected. Rensink addressed the question using a very simple experimental design. Instead of waiting for subjects to move their eyes before switching images he interleaved a very brief presentation of a plain gray image in between presentation of original and manipulated pictures (see **Figure 1**). The brief gray image is, effectively, substituting for motion blur. Rensink was able to alternate back and forth between the two versions of an image repeatedly and, provided there was a blank gray screen between each change, subjects would fail to notice large changes to an image over large numbers of alternations. There was no need to eye-track and subjects were free to move their eyes while trying to detect what was changing in the image.

In Rensink's flicker paradigm the change between images is never directly visible to the subject. It is possible that subjects' failure to detect the change might be due to some form of masking occurring between the gray frame and the changed part of the image. To test whether masking effects might account for change blindness O'Regan et al. (1999) developed a variant of the flicker paradigm that did away with the interleaved gray frames. Instead, every time the image changed a number of small, high-contrast, checkered patched appeared briefly at random locations in the image. O'Regan and his colleagues refer to these patches as 'mudsplashes' in analogy to the effect of mud splashing on a car windscreen. The mudsplash patches did not cover the part of the image that changed but, nevertheless, subjects were still unable to detect the

Figure 1 A schematic illustration of the change blindness flicker paradigm. The observer is presented with the images (a), (b), (c), and (d) in quick succession, for example for half a second each. The presentation repeats in the same sequence until the observer detects that change made between images (a) and (c). Notice that the middle storey of the car-park in the upper right background has been removed in image (c). Observers typically find such changes extremely difficult to detect and may take hundred of repetitions of the sequence before they spot the change.

change. Masking cannot, therefore, account for change blindness.

One explanation for the effectiveness of both the flicker and mudsplash paradigms is that they both prevent the change in the image from attracting visual attention. If one simply alternated between two versions of an image without an interleaved frame then the elements of the image that change produce a spatially localized visual transient that can attract attention to the location of the changing part of the image. In the flicker paradigm the entire image changes to gray when the interleaved frame is presented and so there is no localized transient that can specifically guide attention to the location of the change. In the mudsplash paradigm the changing part of the image is not obscured and so does generate a localized transient, but at the same time as this transient occurs the mudsplashes are also producing competing highly salient transients and so reducing the chances that the changing part of the image itself will attract attention. Changes in a scene only attract our attention if they are abrupt. When changes occur gradually then even in the absence of any other manipulation they are likely to be missed (see e.g., Simons et al., 2000).

The mudsplash paradigm allows explanations of change blindness beyond disruption of attentional capture to be tested. In a picture of a real-world scene some aspects of the image will be more important, in terms of their meaning, than others. In a picture of two people having dinner al fresco the people are more important to our understanding of the image than the position of clouds in the sky, even though the clouds may form a larger part of the image in terms of area. O'Regan et al. used a variant of the mudsplash paradigm to intentionally draw subjects' attention to the location of a change within an image. They positioned a single mudsplash at the location of the change. The change was therefore obscured, but the single mudsplash drew subject's attention to its location. When the change occurred in a part of the scene important to its meaning subjects could identify the nature of the change immediately. This, again, implies that masking cannot explain change blindness. Interestingly, however, if the change (and accompanying mudsplash) occurred in a part of the image with little significance for its meaning subjects were often unable to identify the nature of the change. Even though subjects were attending to the change location they were not encoding that part of the environment with sufficient detail to know what had changed there. This implies that the richness of our visual representation varies according to the significance we attribute to different parts of the scene.

All of the paradigms discussed above point to the importance of attention, or specifically the lack of it, in inducing change blindness. Lack of attention cannot, however, be the whole story. Even when the changing object is attended subjects can fail to notice that an object has changed if the moment of change is not visible. One of the most dramatic demonstration of this is from a study by Simons and Levin (1998) in which subjects fail to notice that the (real) person to whom they are talking changes from one individual to another when the switch is obscured by a visual interruption (a door is carried between them). Similar failures to detect change occur when films cut from one view of an actor to another. Detecting a change in an object involves a comparison between the state of the object before and after the change. There are a number of ways in which this comparison could fail. Memory is clearly involved in comparing the current state of an object and its state in the past.

We have seen that the psychological significance of objects affect the likelihood that changes to them are detected. Change detection involves making a comparison between the current and previous states of an object so perhaps both attention and significance affect memory for the initial state of objects. It is certainly the case that factors known to influence memory affect change blindness. For example, we become less likely to detect changes in items, the longer the interval between the time they were fixated and the time at which the change occurs (Hollingworth, 2004) – there is a 'recency effect' in change blindness. Of course, the fact that a change can go undetected for considerable time and yet eventually be recognized demonstrates that change blindness is not solely a failure to encode memories. Changes in a scene may interfere with memories that have already been encoded or encoded memories of objects may only be retrieved when those objects are attended. Informing subjects which object in a scene may have changed using a visual cue presented after the change can have no effect on encoding but subjects' ability to indicate whether the cued object changed was markedly better than their ability to report whether *any* object in the scene had changed in the uncued condition (Hollingworth, 2003). Of course, some changes may remain undetectable even when a subject is cued to report changes in a specific object. As we have seen in the early experiments of McConkie and Zola (1979) in which a change in the case of letters was undetected, change is only detectable if the property that changed has been encoded and retrieved. There is, however, evidence that changes to visual properties that have been encoded may not always be enough to permit change detection even when retrieval is cued. Fernandez-Duque and Thornton, 2000 showed that when subjects report that a specific object has not changed they take longer to respond if the object did in fact change than they do if the object remained the same. Laloyaux et al. (2008) presented subjects with photographs each showing three people. Unbeknown to the subjects the emotional expression on one of the faces changed gradually over the period that the photograph was being viewed. At the end of the stimulus presentation the subjects are shown one of the three faces from the photograph and asked to report whether it has changed. They are also asked to report which of five versions of the face they saw. Subjects fail to detect the change in the majority of trials, however, even when the change is undetected they choose the face from the five examples that most closely matched an expression seen during the course of the undetected change rather than the expression seen either at the start or at the end of the presentation. Information about a changing object may therefore be encoded in memory and remain to some extent intact despite changes in the stimulus and still not drive change detection.

Theories

It is clear from the variety of paradigms in which change blindness can be demonstrated that both attention and visual short-term memory play a part in determining whether or not

a change will be detected. Explanations couched solely in terms of attention or solely in terms of memory (e.g., the proposal that the representation of a scene after a change completely overwrites prior representations) are not, however, able to explain all aspects of change blindness. A number of theories propose that combinations of attention, memory, and the significance of objects within the scene determine whether or not changes in these objects will be detected.

Change blindness can be explained at a number of different levels. Hollingworth (2003) and Mitroff et al. (2004) specifically address the issue of *why* changes are missed. Their explanations are couched in terms of the importance of changes and their relevance to the task of interpreting a scene. Changes may be missed because they do not contribute to the meaning of a scene and so remain largely unattended. In many examples of change blindness the undetected changes, although often large, do not affect the meaning of the scene as a whole. The precise location of the horizon in scene showing a sailing boat cutting through the waves has no impact on our interpretation of the scene, although moving the horizon may change a large area of the image. One can then go on to consider why attention may be necessary in order to detect change.

Many authors start from the position of assuming that the initial preattentive visual representation of objects is transitory. It is something akin to iconic memory that decays rapidly. This representation may already be parsed into objects by some scene segmentation process, but if objects are segmented they still have no meaning, their contents are just visual details. Perception involves taking this raw representation of objects' components of and transforming it into a stable representation in which the meaning of the scene and the object in it are represented. The notion that attention serves to bind features into object representations has a long history and many theories of change blindness and of scene perception in general emphasize this dissociation between a rich preattentive experience and a sparse cognition of the gist of scene. We only notice changes in the sparse semantically meaningful representation and only access visual detail within the scene as we need it – we do not store a representation of visual detail but obtain from the world.

Rensink (2000), for example, suggests that before attention is deployed our representation of the portion of a scene that we are currently looking at takes the form of 'proto-objects' containing the features of objects. This representation is rich in that all of the information about the features of the object are present; however, these features are not bound together into coherent representation encompassing the identity of the specific object. These mutable representations only reflect the current content of the world. As things change in the world, so do their proto-object representations and so, in the normal course of events, changes will be undetectable as there is no stable memory for these proto-objects. If, however, attention is focused on an object then its representation is stabilized – the component features of the proto-object are used to identify it. In this model it is the representation of the proto-objects that is rich containing all the details of their visual properties. The representations that are formed when a proto-object is attended are sparse – it is as if they are merely labels identifying the objects and a few of their key properties. Once attention is withdrawn from an object its representation reverts to that of a proto-object. Attention has only limited capacity and so we can only maintain stable representations of very few objects at any one time.

A key aspect of these models is the fragility of visual memory. The basis of change blindness in these models is that object representations dissolve back into unbound collections of features as soon as attention is withdrawn from them. It is not therefore possible to make comparison with previous states of objects after attention has been withdrawn from them. Experiments in which change blindness is eliminated when location of a change is cued after it has occurred, such as those of Hollingworth described previously, seem to pose a problem for models based on the fragility of memory. If we are told which object has changed after the change occurred we are still able to recover memory of its prior state. It appears, however, that in normal circumstance we simply do not recover these memories.

Change blindness was discovered in the course of work on the integration of visual information across saccades and it is work still focused on this problem that may explain our failure to use what visual memories we have in change detection. One remarkable feature of the visual system is the efficiency with which we correct inaccurate saccades. If, when we move our eyes to fixate a target, our gaze misses the intended location we make a corrective saccade almost immediately. Moreover, we do not notice that we have done so. The mechanisms of corrective saccades have been studied by intentionally moving visual targets as a subject is making a saccade toward them. Again, these movements typically remain undetected. It has been suggested that one of the assumptions built into the visual system, a Bayseian prior, as it were, applied in interpreting the visual stimulus, is that objects remain stable in identity and position across saccades. It is far more likely that a saccade is slightly inaccurate than it is that an object moved or changed during the very brief time it takes to make the saccade to it. So, although we may have visual memory for currently unattended objects, the visual system does not access these memories unless there is strong evidence against the assumption of object stability. This was first demonstrated by showing that movements in the position of a saccade target that were normally unnoticed became detectable if the entire visual display blanked briefly just after the competition of saccades (Deubel et al., 1996). This blanking is a strong cue that stimuli are not stable. During normal vision, however, there is a very strong bias in favor of object stability and so although information about currently unattended objects may potentially be available in visual memory it will not normally be accessed and hence normally changes in the scene that do not capture attention may be missed.

Related Work

Change blindness is often used as a tool in studies aimed at assessing exactly which properties of a stimulus capture attention and are hence immune to change blindness (e.g., Cole et al., 2004). Understanding our abilities to detect or miss changes has obviously application in the real world. Studies using change blindness paradigms have shown that we are poor at detecting changes in real-world scenes. Importantly,

however, we are more likely to detect changes in portions of a scene that are important for a given task. This means that when driving, for example, we may be poor at detecting changes in advertising billboards (which we hope have relatively low importance) but we are better at detecting task-relevant changes such as the appearance of a cyclist on the road (Velichkovsky et al., 2002). We are, moreover, capable of evaluating the complexity of scenes and modifying the level to which we intentionally monitor a scene for changes (Smilek et al., 2008).

Change blindness is one of a group of phenomena in which the effects of attention influence our ability to detect events. In 'inattention blindness,' subjects voluntarily focus their attention on a demanding task. Large changes in the scene can go unnoticed even when those changes occur at the point of fixation (Mack and Rock, 1998). One of the most celebrated demonstration of this is reported in Simons and Chabris' (1999) paper "Gorillas in our midst." Observers are asked to keep track of the number of times a basketball is passed between one group of players, dressed in white, and to ignore passes between player dressed in black. In the middle of the movie a man dressed in a gorilla suit walks across the scene in full (and beats his chest). Remarkably a large proportion of observers fail to notice the unattended gorilla. Variants of this task (Drew et al., 2013) have shown that radiologists when searching a CT-scan for one particular abnormality could miss other unexpected features in the scan (in this case, an image of a gorilla).

Our ability to detect stimuli is also, somewhat paradoxically, reduced just after we have attended to a stimulus. In a paradigm known as the 'attentional blink' subjects are shown a sequence of stimuli, typically letters, presented rapidly one after another and asked to respond when a specific target appears (Raymond et al., 1992). They are then asked whether a second type of stimulus appeared in the sequence at any point following the appearance of the target. Subjects' ability to detect this second stimulus is greatly reduced if it appears in the half-second or so immediately following presentation of the target letter. It is suggested that once attention has been attracted to the target there is a period immediately following during which it cannot be reallocated to the remaining of the stimulus stream.

The common theme to all of these phenomena is that unattended stimuli are poorly detected. This may lead one to conclude that attention is necessary for the conscious detection of a stimulus. This is an especially difficult hypothesis to test as to falsify it one must show that stimuli can be consciously perceived in the absence of attention. Measures of attention are always relative. We might, for example, show than a cued stimulus is processed more effectively that an uncued one. We cannot, however, conclude that the uncued stimulus is completely unattended. Li et al. (2002) conducted an experiment in which subjects focused on a primary task but occasionally had to report properties of probe stimuli presented in peripheral vision. They titrated the difficulty of the central task until performance in the probe task was at a minimum. Their rationale was that attention must now be maximally focused on the central task. They then showed that subject could consciously make complex categorizations of images shown in the periphery (e.g., report whether a scene contains a vehicle). The results are interpreted as showing that attention is not strictly necessary for conscious detection of stimulus properties. Note that, in contrast to most change blindness experiments, the peripheral stimuli in Li's study are important to the subject even though they are unattended.

In conclusion, change blindness and related phenomena demonstrate the importance of attention in recovering a rich representation of objects within a scene. Information from objects that are no longer attended may remain in visual memory but is not routinely accessed. Attention gates access to the information required to detect changes in those objects.

Charisma and Charismatic

Abstract

Charisma is associated with the sociology of Max Weber, especially his typology of authority and legitimacy. Weber developed his famous contrast between tradition, charisma, and legal-rational authority. Charisma was seen to be a revolutionary form of authority, and charismatic religious leaders claimed authority on the basis of an extraordinary dispensation. With the death of the charismatic leader, followers either abandoned the movement or it became more traditional and eventually even legal-rational. Weber called this process the 'routinization of charisma.' There is much debate as to whether charisma still operates in modern society, and whether the theory can be generalized to Asian religions.

'Charisma' or 'gift of grace' is a theological notion that has been widely used in the social and religious sciences to either describe the hierarchical organization of religious roles or explain the growth and development of social movements based on religious inspiration or the basis of authority and leadership in society generally. In its strictly religious context, it means a divinely conferred power, being derived from the Greek *kharisma* (*kharis*, favor or grace). Charismatic power is associated with the idea of the sacred as a force in human affairs. A person in possession of charisma is thought to have a talent, for example, in terms of healing or prophecy. In anthropological research, there has been considerable interest in 'shamanism' as a form of charismatic authority that depends on a capacity to have visions and to perform healing (see Eliade, 1964). In sociology, it is conceptually part of an analytical framework that is concerned with understanding large-scale changes in religious institutions and the foundations of authority.

The Sociology of Charisma

In the sociology of religion, the study of charisma has been closely associated with Max Weber (1864–1920), who adopted the idea from the historical and theological research of Rudolf Sohm and Karl Holl, who in turn had developed the concept in their analysis of Canon law. Weber wrote that "'the concept of charisma' (gift of grace) is taken from the vocabulary of early Christianity. For the Christian hierocracy Rudolf Sohm, in his *Kirchenrecht*, was the first to clarify the substance of the concept, even though he did not use the same terminology. Others (for instance, Holl in *Enthusiasmus und Bussgewalt*) have clarified certain important consequences of it. It is thus nothing new" (Weber, 1978, pp. 1, 216). Despite Weber's modesty about the adoption of the idea, it became a fundamental dimension of his analysis of authority and had far-reaching consequences for the development of the sociology of religious institutions. Weber generalized the idea and grasped its radical implications for the study of social and political change in human societies.

In the rise of religion, certain individuals are recognized as having a capacity to experience ecstatic states that are regarded as the precondition for healing, telepathy, and divination. It is primarily through "these extraordinary powers that have been designated by such special terms as 'mana,' 'orenda,' and the Iranian 'Maga' (the term from which our word 'magic' is derived). We shall henceforth employ the term 'charisma' for such extraordinary powers" (Weber, 1963, p. 2). Such charismatic power either is inherited as a natural endowment or is acquired by extraordinary means. The religious talent in both cases is a substance that may remain dormant in a person until it is aroused by asceticism or trance.

Weber did not dwell on these features of charisma in folk religion because he wanted to employ the term to understand the secular dynamic of authority and leadership in social institutions. His main intention was to compare and contrast three types of authority: charismatic, traditional, and legal-rational. As we have seen, charismatic authority rests on the ability of a leader to inspire disciples in the belief of the authenticity of a calling. In practical terms, an authentic claim is validated by a talent such as healing, but this alone cannot be the basis of authority. In the case of genuine charisma, a follower has a duty to accept the authority of a leader. In *Economy and Society* (Weber, 1978, pp. 1, 241), the term charisma is applied to a certain quality of an individual personality by virtue of which he is considered extraordinary and treated as endowed with supernatural, superhuman, or at least exceptional powers or qualities. Traditional authority involves the acceptance of a rule that expresses a custom, namely, an established pattern of belief or practice. Finally, legal-rational authority is typical of bureaucracies in which formal rules of conduct are underpinned by procedural norms. These forms of authority are in turn forms of compliance. Tradition depends on compliance through empathy, legal-rational authority rests on rational argument, and charismatic authority and leadership require inspiration. Weber provided many diverse illustrations of charismatic leaders, including Jesus Christ, Mohammed, Napoleon, Stefan Georg, and the Chinese emperor. Although the cases were heterogeneous, he argued that charismatic authority is confronted by a common problem of succession with the death of the leader. Charismatic authority is thus unstable. With the demise of the charismatic leader, the disciples typically disband, but occasionally a solution for continuity will be developed. In the case of the Christian Church, Weber argued that the charismatic authority of Christ was invested in the Church itself (as the body of Christ), and thus the bishops who control the 'keys of grace'

 http://dx.doi.org/10.1016/B978-0-08-097086-8.84003-9

enjoy a vicarious authority. This 'institutionalization of charisma' becomes over time increasingly formal, bureaucratic, and impersonal. As the charismatic power of Christ becomes transformed into a set of formal procedures and bureaucratic rules, Weber spoke of the 'routinization of charisma.'

Forms of Religious Association

Weber's account of charisma was also an important component of his sociology of religion within which he attempted to identify different religious roles and patterns of organization. For example, in *Ancient Judaism* he distinguished between the prophet who, as a charismatic figure, has a personal calling, and the priest who has authority by virtue of his service in a sacred tradition (Weber, 1952). The prophets, who often emerge from the ranks of the priesthood, are unremunerated and depend on gifts from followers. Weber also distinguished two forms of prophecy as represented, on the one hand, by Buddha and, on the other, by Zoroaster and Muhammad. The latter are involved in 'ethical prophecy' and are conceived as instruments of God. These prophets receive a commission from God to preach a revelation and demand obedience from their disciples as an ethical duty. By contrast, exemplary prophets demonstrate to their followers a salvational path through the example provided by their own lives. Exemplary prophecy was, according to Weber, characteristic of Asia; ethical prophecy, of the Abrahamic religions of the Middle East. Weber's analysis of charisma with respect to ethical prophecy in the Old Testament has been subject to considerable criticism (see Zeitlin, 1984), but his conceptual framework continues to influence both sociology (see Lindholm, 1990) and anthropology (see Werbner and Basu, 1998).

This discussion of charisma with respect to different social roles should be seen as part of a larger sociological debate about the forms of association that characterize the social organization of religious belief and practice. Weber wanted to argue that any group that is subject to charismatic authority forms a charismatic community (*Gemeinde*) and that such a community is inherently unstable. With the death of the leader, the group either dissolves or charisma undergoes a process of routinization. The disciples have no career, formal hierarchy, offices, or qualifications. The church that provides the organizational context of the priesthood is very different. Ecclesiastical organizations require a hierarchical administration of the 'charisma of office' in which there are definite stages in clerical and administrative careers. It is clearly the case that Weber's sociology of charisma should be understood as somewhat parallel to Ernest Troeltsch's 'church-sect typology' in which there is a historical oscillation between the evangelical sects and the bureaucratic churches (see Troeltsch, 1931).

Charismatic Movements

Because Weber believed that in modern societies legal-rational authority would become dominant, tradition and charisma were regarded as early forms of authority and thus as characteristic of premodern societies. The decline of charisma is thus associated with the idea of secularization. The notion that charismatic authority was not a resilient aspect of modern society was in turn a function of Weber's pessimistic understanding of social change in terms of secular rationalism and the erosion of religious meaning. Against Weber's assessment, the late nineteenth and twentieth centuries were profoundly influenced by charismatic movements. Charismatic renewal has been a common theme of diverse religious movements in 'primal societies' and in the industrial societies of Europe and North America. The collapse of aboriginal or tribal societies under colonial settlement saw the spread of charismatic movements against the supremacy of White-settler societies such as the Ghost Dance among the Cheyenne and Sioux tribes of the American Plains. A Paiute prophet called Wovoka had received a vision in which through ritual dance the dead would return to restore the pristine culture of native societies. This anti-White charismatic movement subsided after the murder of Sitting Bull and the subsequent massacre of his followers at Wounded Knee in 1890. Charismatic leadership has also played a significant role in those new religious movements that have been a response to the social and economic disruptions associated with the decolonization of the Third World (see P. Worsley, The Trumpet Shall Sound, 1970).

In contexts of rapid social change, charismatic leadership is an important component of so-called revitalization movements that function to create an effective transition from tribal to urban society. However, charisma is also associated with religious forms that are a response to personal alienation, isolation, and meaninglessness in the developed, industrial world. One illustration is the Family, whose members were disciples of Charles Manson and operated in southern California in the late 1960s. Manson, who was a social dropout with a criminal record, provided a message of personal liberation based on mind-expanding drugs and found a receptive set of disciples in the cultic milieux of the American counterculture. The Manson Family offered disoriented disciples the experience of an absolute community that depended on a powerful ideology and indoctrination (see Schreck, 1988). Another American illustration would be Jim Jones and the People's Temple (see Weightman, 1983). These manifestations of charisma in modern society are closely associated with the dislocations of youth culture, the anomie of the modern city, and the spread of personal alienation. Charismatic figures can also enjoy a global following with modern communication and international travel. For example, Sathya Sai Baba (1926–2011), who was born in Puttaparthi, a remote Indian village, gained a global following from a range of different religious traditions and built numerous religious centers around the world. He claimed to be an incarnation of the Indian saint and Muslim faqir Shirdi Sai Baba, announced that he was the 'Cosmic Christ,' offered healing to the sick, and showered his disciples with gifts (see Srinivas, 2010).

Charisma is not exclusively of interest to sociologists of religion. It plays an important role in political sociology. Commenting on Weber's discussion of charisma in the famous 'Politics as a vocation' (Weber, 2009) – a lecture from Munich in 1919 – Peter Baehr (2008: 90) suggests that Weber implied a tripartite division between religious, military, and political dimensions. What Weber called the city-state demagogue and the parliamentary party leader were unique to the West. British Prime Minister William Gladstone (1809–98) was in Weber's

eyes a grand demagogue whose charismatic powers wooed the masses, allowing him to become a plebiscitary dictator.

Conclusion: Charisma in the Information Age

Weber's analysis of charisma has produced a rich legacy of sociological research, but there are serious conceptual problems associated with its application in contemporary society. The concept of the charismatic movement is used to describe a variety of revivalist, nativist, messianic, and healing movements. There is considerable debate in sociology and religious studies about whether charisma in modern society is degraded and inauthentic (see Wilson, 1975). The term is frequently employed to describe the fleeting popularity of political leaders whose social appeal is constructed by campaigns in the media. Whereas charisma in traditional societies arises spontaneously in the collective enthusiasm for divinely inspired leaders, in modern politics it is inevitably the product of deliberate orchestration of the media. The notoriety of the Manson Family and the People's Temple was a conscious product of media attention. However, this argument indicates a persistent issue in charismatic movements, namely, how to distinguish between genuine and false claims to religious authority. Biblical warnings against 'false prophets' recognized the fact that disciples could be misguided. While the term has been implausibly stretched to describe a diverse and heterogeneous range of leaders in the twentieth century from Adolf Hitler to John F. Kennedy, it remains a basic concept in sociology and in religious studies.

Abstract

Charisma is the extraordinary and revolutionary power that is given to the one chosen to lead. Charismatic leadership may be religious, political, artistic, or social, and it is often temporary: the person's charismatic power lasts only as long as he or she is able to perform extraordinary tasks. When the person is regarded as no longer being successful, the charismatic power is considered to have been withdrawn. The power of charisma has long been recognized, but its study is relatively recent. The concept of charisma has been broadened extensively in the last decade or two, with the result that it has lost some of its traditional characteristics.

Charisma is the extraordinary power that is supernaturally given to a specifically chosen person. The charismatic individual was a magician, a prophet, a shaman, or a particular kind of religious leader. The charismatic person was recognized as being special by virtue of the special powers that were given to him or her. These powers were highly unusual, and were often transitory. Charisma seemed to have been endowed in an individual for a short time and then withdrawn rapidly. Charisma was an unstable power and seemed resistant to permanence and transference. Its instability, its intensity, and its unusualness contributed to its allure.

Much of this article will focus on Max Weber because, as Stephen Turner has written, "Max Weber is the original and sole source of the social science concept of charisma (as distinct from the religious concept)… ." (Turner, 2011: p. 82).

Charisma, Origins of

Max Weber was the one who introduced the notion of charisma into sociological discourse, and he paved the way for expanding its use into the general public, but he was not the originator of the term. Weber was not always concerned with identifying the sources for his ideas, and when he did, it is important to examine them for they frequently shed considerable light on the issue that he addresses. This is particularly true regarding the notion of charisma, because his theological sources do not simply deal with charisma as a religious concept, but indicate qualities that become important for Weber's own social and political notion of charismatic authority.

As a religious concept, charisma does not have a long history. It does not have an entry in either the first (1909) or the second edition (1927) of *Religion in Geschichte und Gegenwart*, nor in the third edition (1899) of the *Realencyklopädie für protestantische Theologie und Kirche*. Instead, one is directed to the entry 'Geistesgaben.' or 'spiritual gifts.' The reader is referred to I Corinthians 12, where 'spiritual gifts' are briefly mentioned. What is important is that these are miraculous gifts, and they come directly from God. They can be utilized for the benefit of the receiver or, more generally, for the receiver's community (Cremer, 1899: pp. 460–463). Weber's two acknowledged sources represent each of these two points of view; Karl Holl's focus on charisma is in relation to the soul of the receiver, and Rudolf Sohm's is on its importance for the community.

In the first part of *Wirtschaft und Gesellschaft*, Weber explicitly mentions Karl Holl and Rudolf Sohm in connection with the concept of "'Charisma' ('Gnadengabe')" (Weber, 1922: p. 124). Weber's reference to Holl occurs only once, and it is to his early work *Enthusiasmus und Bussgewalt*. As the subtitle makes clear, Holl's book is devoted to Greek monks and specifically to Symeon, a Greek monk living about 1000 AD. Symeon was an ascetic, and he considered ascetic suffering to be a type of cleansing that then resulted in a closer relation to God. For Symeon, the world of the senses was unimportant; the real world was invisible and was filled with devils and spirits. Symeon believed that charisma was a gift from God and that its spiritual effects helped him in his struggle with the demons (Holl, 1898: pp. 143, 148–150). It was a 'spiritual gift' that allowed the monk to concentrate on what was most important to him – his own spiritual salvation (Holl, 1898: p. 153).

The second, and more important, source for Weber's conception of charisma was the Church historian and legal scholar Rudolf Sohm (Kroll, 2001: p. 51). Sohm is more important because Weber cites him often. Weber makes reference to his notion of charisma in the early part of *Wirtschaft und Gesellschaft*, but also in the main section on charisma (Weber, 2005: p. 462). Furthermore, he specifically cites Sohm's notion of charisma as indicated in the account of his Vienna lecture "Probleme der Staatssoziologie" (Weber, 2005: p. 755). Finally, he explicitly mentions Sohm and the treatment of charisma in his lecture course "Allgemeine Staatslehre und Politik (Staatssoziologie)" as well as in the posthumously published "Die drei reinen Typen der legitimen Herrschaft" (Weber, 2009: pp. 77–79 and Weber, 2005: p. 735). Second, Weber spells out his debt to Sohm: Sohm was the first scholar to investigate the notion of charisma from a "scientific view point," and Sohm's treatment of it was "brilliant" (Weber, 2005: p. 735). Third, Sohm not only treated the concept from a "purely historical" perspective but also indicated its "sociological specialty of this category of power structures" (Weber, 2005: p. 462). Sohm intended to indicate the importance the concept played in the early Church and thereby show the fundamental difference between the early believers and the later Catholic Church. Holl's

discussion of eleventh-century Greek monks and Sohm's investigation of charisma in the early Church may not seem to have much in common; however, both noted that the revolutionary power of charisma was used against institutions. That is why Holl writes of the opposition between "office and spirit" and why Sohm describes the contradiction between the free world of the spirit and the dominating Church law (Holl, 1898: p. III and Sohm, 1892: p. X). Sohm explains that 'ecclesia' does not mean Church, but it does mean "God's people" and he distinguishes between the church's structure and the real notion of church. The real church is a gathering of believers – where "two or three come together" (Sohm, 1892: pp. 19–20). Charisma is a God-given gift, and it requires recognition. However, there can be no talk of 'legal obligation'; rather, there is only the 'the love of the highest.' Charismatic power requires 'free recognition' and 'free obedience'; thus, it stands in direct opposition to the 'demands of the law' (Sohm, 1892: p. 27). Sohm's pro-charisma and antilegal argument about the early Church provoked a lengthy and heated discussion with the noted Church historian Adolf Harnack. Thomas Kroll maintains that this debate prompted Weber to think more fully about constructing his typology of domination (Kroll, 2001; Weber, 2005: pp. 37–41). Whether this is true is not important here; what is important is that Karl Holl and Rudolf Sohm both regarded the notion of charisma as being fundamentally important with its opposition between spirit and organization, not just for theology but also for society. In his introduction to the English translation of *Wirtschaft und Gesellschaft*, Guenther Roth maintained, "He [Weber] secularized Rudolf Sohm's notion of the charisma of the Christian Church" (Weber, 1978: p. XCVI). It was Weber who introduced it to a wider audience.

Weber's Concept of Charisma

Weber frequently discussed concepts by setting out their opposites, and his discussion of charisma follows this pattern. If anything, Weber believed that charisma could be understood only by contrasting it with very different but related concepts (see Adair-Toteff, 2005). There are three such concepts, all of which fall under the category of Herrschaft. The term 'Herrschaft' is resistant to translation, but it incorporates 'domination,' 'rule,' 'authority,' and 'leadership.' Weber defines Herrschaft as the likelihood that one will obey a specific order given by a specific person (Weber, 1922: pp. 28, 122; Weber, 2005: pp. 135, 139, 727; Weber, 2009: pp. 74, 75). Weber acknowledges that people will obey an order for a variety of reasons: out of self-interest, out of simple convention, or even out of sheer habit (Weber, 1922: p. 122; Weber, 2005: p. 726). However, Weber's concern is with those who obey because they acknowledge the validity of that authority, hence his concern is with 'legitimate' Herrschaft. In his view, there are only three 'pure' forms of legitimate Herrschaft, and he readily acknowledges that they are rarely found in reality. Because they are rarely found in reality, Weber is convinced that it is even more imperative to offer "clear concepts" of these types (Weber, 1922: pp. 123–124; Weber, 1992: pp. 160–161; Weber, 2005: p. 726).

The first type of legitimate Herrschaft is 'legal,' and it has a significant number of features. It is based upon rational rules, and the person who interprets and implements these rules is fully trained; the person has had a rigorous education and has proven his or her expertise by passing exams. These are people who then hold an office and are part of a hierarchy. The officials who make the determinations must follow objective rules, so these determinations are never arbitrary. The determinations are totally independent of the person and are neither made for or against that individual. As Weber repeatedly writes, these decisions are made "without hate or love" ("sine ira et studio") (Weber, 1922: p. 129; Weber, 2001: pp. 400–401, 429; Weber, 2005: pp. 187, 727). The rules are always in continuous effect; as a result, legal Herrschaft is both stable and permanent (Weber, 1922: pp. 125, 127; Weber, 2005: pp. 726–727). These are all important components of legal Herrschaft, but the most defining one is the notion of competency. Weber emphasizes this in virtually every single account of legal Herrschaft (Weber, 1922: p. 125; Weber, 1992: pp. 160–161; Weber, 2005: pp. 136–137, 726; Weber, 2009: pp. 78–80). The second type is 'traditional' (or even 'conventional'), and it shares a number of features with legal Herrschaft (Weber, 1922: p. 123). It is also stable and permanent; Weber speaks of the "eternal laws" (Weber, 1992: p. 160). Weber grants that the traditional Herrschaft is personal, but he also stresses that he is mostly restricted by tradition (Weber, 2009: pp. 76–77, 82). The patriarch is able to introduce new laws as long as they do not conflict with the 'holiness' of the long-established order and he also has enough respect from the others (Weber, 1922: p. 133; Weber, 2005: pp. 149, 729). While not as strictly formal as legal authority, traditional authority tends not to be arbitrary, and the decisions are based on more than simply who the person is. But Weber stresses that traditional Herrschaft lacks the objective and dispassionate competency of the trained official, and it lacks clear and rational regulations (Weber, 1922: pp. 131–132).

Weber spends a considerable amount of effort explaining what charisma is not: it has no official, it has no training, and it has no hierarchy. It has no rules, it has no competency, and it has no legal principle. It is not impersonal, it is not permanent, and it is not stable. These are all important differences, but the single most important difference between charismatic and legal and traditional Herrschaft is that it is extraordinarily unusual. Weber insists that both traditional Herrschaft and legal Herrschaft are "specifically *ordinary* (*everyday*) (*Alltags-*) forms of 'Herrschaft.'" Traditional Herrschaft has existed forever, and while legal Herrschaft is a relatively modern phenomenon, it is found everyday in many parts of the Western world. In marked contrast, charismatic Herrschaft is extremely rare, or, as Weber says – it is always "unusually extraordinary" (*Außeralltaglich*). Weber makes this point or some variation of it repeatedly (Weber, 1922: pp. 140–1411; Weber, 1989: pp. 99, 175; Weber, 2001: pp. 315, 355; Weber, 2005: pp. 739, 740; Weber, 2009: pp. 90, 91; see Shils, 1965: p. 199; Bendix, 1977: p. 299; and Adair-Toteff, 2002: p. 194). However, the phrase 'unusually extraordinary' can be applied to a number of things: a person's height or weight, an animal's speed or strength, or a storm's range and force. In contrast, charisma also has the power to awe. That is why Weber believes that charisma is such a revolutionary power; he called it the "specifically 'creative' revolutionary power in history" (Weber, 2005: pp. 468, 482; Riesebrodt, 2001: p. 151). Late in his

life, Weber insisted that there were only two "revolutionary" powers that were historically important: rationality, which "comes from above" and charisma, which "comes from within" (Weber, 2009: pp. 92–95).

The charismatic person convinces others of his/her unique power by performing magical feats, by offering revelations, or by doing heroic acts (Weber, 1922: pp. 140, 141; Weber, 2005: p. 737). The individual is regarded as charismatic only as long as he/she is successful; as soon as there is a failure, there is a risk that the others will withdraw their recognition and stop obeying instructions and orders. The warrior who begins to lose battles, the magician who can no longer conjure tricks, and the political leader whose words have lost power are some examples of the person who has lost his/her charismatic power. Charisma is predicated upon the recognition of the person's charismatic powers and that this recognition is subject to change; it is highly personal and very temporary.

Weber contrasts the uniqueness and instability of charisma with the ordinariness and regularity of everyday life. Charisma is opposed to both traditional and bureaucratic rationalism (Weber, 2005: p. 542). Economic, familial, and societal concerns are alien to the charismatic leader; money, family, and order are not important to him/her (Weber, 2005: p. 484; Weber, 2009: p. 93). The demands of everyday living are antithetical to the extraordinariness of charisma, and they serve mostly to compromise its power. Every compromise with the everyday order alters the character of charisma in a very negative manner (Weber, 2009: pp. 94, 95). In a passage remarkable for its intensity, Weber describes how charisma's interaction with the material needs of the everyday world diminishes and dooms it: "Each charisma finds itself on this way from a stormy-emotional economic-alien life to a slowly suffocating death under the weight of material interests in each hour of its life and indeed with each growing hour in increasing measure" (Weber, 2005: pp. 488, 489).

Charisma – Transference and Institutions

The instability and lack of permanence in charisma pose the great question about transference: can it be passed on to another individual, or can it be institutionalized? Weber recognized that charisma was broken in its conflict with the demands of everyday life, and it was transformed into "churches, sects, academies, schools" (Weber, 2005: p. 489). Weber cites the example of Jesus appointing Peter as his legitimate 'successor' and directing him to found his 'church' (Weber, 2005: p. 495). Weber notes that the most common way of ensuring that the power of charisma can be passed on is by legitimizing it through the "bond of blood" (Weber, 2005: pp. 517, 740). Weber sometimes refers to this as "Erbcharisma der Familie" (Weber, 2005: pp. 522, 525). Another way of transferring charismatic power is through "Amtscharisma," which Weber defines as the specific conveying of the power through a social institution. While this is predominantly a church, it need not be restricted to just that (Weber, 2005: p. 527). However, Weber points to the Catholic Church as the clearest example of "Amtscharisma" and notes how it is based upon the "authority willed by God" (Weber, 2005: p. 529). Weber contrasts the spontaneity of charisma with discipline. He points to military discipline but also to the economic discipline needed to run a large business (Weber, 2005: p. 556). There is a fundamental tension between the revolutionary power of charisma and everyday routine living (Roth and Schluchter, 1979: p. 37).

There are some scholars who argue that charisma and order and institutions are not diametrically opposed. In the introduction to his *Max Weber on Charisma and Institution Building*, S.N. Eisenstadt admitted that Weber himself stressed the "dichotomy" between charisma and social organization, but he emphasized that Weber actually believed that the two were fundamentally interrelated (Eisenstadt, 1968: p. ix). Eisenstadt points to two types of creativity – one in which an idea is nurtured for a long time and finally comes to fruition, and the other, which seems to be close to being spontaneous. However, he insists that both can come about only within a permanent social framework (Eisenstadt, 1968: pp. xvi, xvii). Eisenstadt notes that the charismatic leader creates in freedom but leaves an impact on the institution through routinization. He suggests that this process is cyclical – charismatic power rises up against the ordinary, becomes routine, and then rises again (Eisenstadt, 1968: p. xxi). In "Charisma, Order and Status" Edward Shils also points to the social need for order and looks to Weber's own examples for transferring charisma (Shils, 1965: pp. 202, 203). However, Eisenstadt appears to underscore the human need for order found in institutions and to overlook the uniqueness and awe-inducing power that are the marks of charisma.

Religious and Political Charismatic Leaders

Charismatic leaders are both very important and rather rare, so it is instructive to note those who Weber specifically identifies. Sometimes Weber simply names them, while other times he spends some time discussing them. He orders them into three types: artistic charisma, religious charisma, and political charisma.

Weber does not devote much time to discussing artistic charisma, but he identifies Stefan George as a poet who possessed enormous charisma (Weber, 1922: p. 142; Weber, 2005: pp. 40, 465; Weber, 2009: p. 93). Stefan George was a firm believer in aesthetics and promoted an "arts for art's sake" philosophy. Before 1900, George had come to be regarded as a modern-day prophet, and this group of followers was referred to as the "Stefan George Circle." Weber appreciated George's separation of art from money, and he respected George enough as a translator to use his rendition of Shakespeare; however, he was highly critical of George's cult-like following. George was charismatic in that he had a forceful personality and a magical way with words. In Weber's opinion, George was too much of a proponent of irrational romanticism, which led his followers to reject sober counsel and instead to seek out extreme emotional experiences (Weber, 1992: p. 34; Weber, 2005: p. 465).

Weber devotes more time to religious charisma, and he identifies several figures from Christianity. Weber draws attention to Jesus and his charismatic power (Weber, 2001: p. 355). Jesus is the one who personifies the rejection of all traditional rules and laws – "It is written but I say unto you." Instead, he introduces the "eternally new," and he gives "new commands"

(Weber, 1922: p. 141; Weber, 2005: pp. 468, 734; Weber, 2009: pp. 92, 93). He may be sent by God, but he is also forsaken by God (Weber, 2005: pp. 466, 734). Weber also singles out St Francis, but he does not explain why he thinks that St Francis is a charismatic figure. What he does suggest is that St Francis' belief in unconditional goodness was a special doctrine that drew people (Weber, 2001: pp. 318, 319). He also notes that St Francis' songs were extraordinarily powerful and thus had an almost mystical effect (Weber, 2001: p. 413). Christians are not the only religious charismatic leaders; Weber also identifies the Buddha and even the Dalai Lama (Weber, 1989: p. 521; Weber, 2005: p. 494).

Prophets, and especially Old Testament Prophets, are repeatedly mentioned by Weber as being charismatic (Weber, 1922: pp. 140–143; Weber, 1992: p. 160; Weber, 2001: pp. 177–180; Weber, 2005: pp. 483, 515, 594, 691, 734–737; Weber, 2009: pp. 90–93). Prophets are difficult to classify; while it seems intuitive to place them in the religious charisma category, Weber often accentuates their political involvement; hence, I place them in the political charisma category (Weber, 1992: p. 161). Like many of the charismatic leaders, the Old Testament Prophets believed that they had been 'called' and that they had been given a mission. Weber refers to this as a "prophetic mission" or a "Godly mission" (Weber, 2001: p. 203; Weber, 2005: pp. 462–464). Weber differentiates the prophet from the priest; the former has been personally called, while the latter has been professionally trained (Weber, 2001: p. 178). Weber does not deny that some priests have charismatic traits, but he emphasizes that these are personal and are not derived from the priestly office. Weber also differentiates the prophet from the magician; the latter's charisma comes through performing magic, while the former's is derived from God-given ethical commands (Weber, 2001: p. 178). Accordingly, the prophet demands obedience out of an ethical duty rather than from any type of law or tradition (Weber, 2001: p. 189). The Old Testament Prophets revealed divine instructions; thus, they were not involved in any political tradition.

Weber does identify several genuine political leaders as possessing charisma: Gladstone and Napoleon (Weber, 2009: pp. 90–93). But it was Pericles who seemed to be the most interesting of the charismatic political leaders, and that was because he combined the power of words with the power of deeds (Adair-Toteff, 2008: pp. 147, 155, 160). Weber reminded us that Pericles was a demagogue, but one who embodied the characteristics of a responsible political leader (Weber, 1992: p. 191; Weber, 2005: p. 736; Weber, 2009: pp. 102, 103).

Evil Charismatic Leaders

For the most part, all of Weber's examples of charismatic leaders are revolutionary, but they also appear to be forces for good. However, there are examples of charismatic leaders who were evil. Charles Lindholm is one scholar who spent considerable effort in discussing the charisma of evil leaders. He emphasized three, all of whom were from the twentieth century.

The name Charles Manson is not normally connected to the notion of charisma, but Lindholm makes this a compelling case. While Manson did not commit any murders himself, his charismatic power was so great that his 'family' members were more than willing to commit any crimes, including murder, that he ordered. There are several things that separate Manson from many other charismatic leaders, but one of the most pronounced was the way in which he shared the power with his disciples. Rather than maintaining distance in order to preserve a sense of awe, Manson seemed to relish drawing his disciples to him and sharing the secrets of his power (Lindholm, 1990: p. 133).

In contrast to Manson, Jim Jones, the charismatic founder of the "Peoples Temple," maintained his authority by being aloof and delegating responsibility to a very close inner circle. The inner circle carried out many of Jones' commands, but it also served to insulate him when there were mistakes. In this manner, Jones was able to maintain his sense of always being right, even when the facts seemed to show the opposite. Like Manson's followers, Jones' followers also gave up much in order to belong, but unlike the Manson 'family,' Jones' disciples were a much larger and more diverse group. They gave their possessions to Jones and followed him from place to place, ultimately to Guyana. While there were the usual middle-class white radicals, many of Jones' followers were impoverished black people. Moreover, the followers were not just young people, but older people were involved as well. As Lindholm points out, the followers came from three generations (Lindholm, 1990: p. 139). As Weber indicated, charismatic leaders care little about money; Jim Jones was totally indifferent to wealth. What he thrived on was power.

The most famous evil charismatic leader that Lindholm discusses is Adolf Hitler. Lindholm stresses that it was Hitler's great power as a propagandist and especially as an orator that brought him so much success (Lindholm, 1990: p. 99). Lindholm utilizes some of Weber's classifications: the focus on Hitler as a person, his personal force, and the religious fervor of his followers (Lindholm, 1990: pp. 100–107). Lindholm is not the only person to emphasize Hitler's charismatic power. There have been a number of recent books devoted specifically to Hitler's charisma: three examples are *Hitler's Charisma: Leading Millions into the Abyss*, *The Third Reich: Charisma and Community*, and *The Dark Charisma of Adolf Hitler*. The point in each is to help explain how and why so many people were not only willing but also even eager to believe in the need for mass killings and genocide.

To Lindholm's list, we can also add David Koresh and Osama bin Laden. The Branch Davidians were ready to die for their convictions, and bin Laden's followers were ready to kill for their beliefs. Both groups were convinced of the power of their charismatic leader and as a result were willing to follow whatever commands their leader gave. Whether good or bad, these charismatic leaders were regarded as possessing a highly unusual power; they were rarities in history. Today, however, charisma has lost that specialness and now is applied to the most wide and varied objects.

'Charisma' Today

The notion of charisma has now gained widespread currency; it is found in hundreds of recently published books (Turner, 2003). Most of those that have appeared between 2010 and 2013 can be divided into three categories. There are some

that are primarily religious in orientation and deal with the notion of charisma in the eternal fight between good and evil; however, the vast majority can be divided into two, overlapping categories. They are in the categories of leadership skills or self-improvement. Examples of the first include *Charisma-Based Leadership: How to Be the Leader That Everyone Wants to Follow*, *How to Be Charismatic: Learn from the World's Most Charismatic Leaders*, and *The Psychology of Human Leadership: How to Develop Charisma and Authority*. Examples of self-improvement are even more plentiful; they include *The Charisma Myth: How Anyone Can Master the Art and Science of Personal Magnetism*; *How to Light Up a Room: 55 Techniques to Help You Increase Your Charisma, Build Rapport, and Make People Like You*; *Art of Conversation: Enhance Your Charisma for Success*; *The Laws of Charisma: How to Captivate, Inspire, and Influence for Maximum Success*; and *The Charismatic Edge: The Science of Confidence, Captivating and Compelling Communication*. These titles indicate the many ways in which the notion of charisma has been altered and expanded since Weber's introduction of it. First and foremost, it is no longer considered a gift; instead, it is now regarded as something that can be acquired, something that can simply be learned. Furthermore, it is no longer that unusual; anyone can acquire charisma – as long as the individual is willing to buy the book that promises it. Third, it is no longer mysterious; instead, it is a science, an art, or even an amalgam of each. Fourth, the fact that charisma was regarded as a fleeting and transitory power has been replaced with the sense that once one has gotten it, one will always have it. This connects to the fifth point; originally, the person was regarded as possessing charisma only so long as that person was successful – performing miracles, winning battles, and the like. As soon as the person failed, the adherents believed that God or the gods had withdrawn that special power. Finally, charismatic power is no longer regarded as extraordinary and highly unusual; instead, the notion has been generalized to mean almost any type of attractiveness, popularity, and even charm (Wikipedia). Thus, the notion of charisma has been generalized; while it can still be applied to various Western and Eastern types of 'charismatic awakening' churches, it is now applied to almost anything. It has now been applied to cars, not just to special ones like the iconic Porsche 911 but also to the Mitsubishi Carisma, which was a play on 'car' and 'charisma.' Charisma is also a brand name for bed sheets, pillow cases, and even towels. It is also a brand name for dolls, toys, collectibles, and jewelry. It has been used as a name of a hair-styling salon. Finally, it is also a woman's name, which strangely enough seems to have been adopted by authors of semipornographic novels (Charisma Knight and Kelsey Charisma) and even an actress and Playmate (Charisma Carpenter). The unfortunate result of all of this is that, as Marta B. Calás (1993) has suggested, we have been "making 'charisma' as *ordinary* as possible"; thus, the idea of it has been so expanded that it is now far removed from Weber's (and Sohm's) original notion of charisma as an *extraordinary* and awesome power. Nonetheless, the concept of charisma continues to play an outsized role in modern society.

Abstract

Philanthropy is defined as a benevolent behavior toward others in the society, usually in the form of charitable gifts. Charitable giving accounts for a significant fraction of income in the US and other nations and is often directly encouraged through government tax policy. This article discusses the motives, causes, and influences of philanthropic behavior. Special emphasis is placed on how government policy – through the charitable deduction on income taxes and through direct grants to charities – can affect the amount of philanthropy in the economy.

Introduction

In 2006, the second richest man in America, Warren Buffett, pledged that over the remainder of his life he would give away 85% of his wealth – at the time, a sum of over $40 billion – to a foundation established by the richest man in the world, Bill Gates. By 2012, the two men have given away nearly $26 billion, and held another $36 billion in assets waiting to be handed out.

These are examples of philanthropic, or charitable, behavior – individuals freely giving money to help others. Most people are, in fact, philanthropists, although not on the scale of the two mentioned above. Through the last few decades, over two-thirds of Americans donated money to charity in any given year, with households giving over 2% of income on average. In 2011, average cash donations to charity were $2227 per married household, and $1303 for single people, making charitable giving a major category of household expenditures.

In addition, the government is an active partner with private donors in funding the charitable sector of the economy. It does this in two ways. The first way is direct grants to charities. In 2009, for instance, charitable organizations reported receiving $140 billion in government grants, or about 10% of total revenue. The second way the government spends money on charity is by excluding income spent on charitable donations from the income tax. The US tax code was modified in 1917 to allow many taxpayers to deduct their charitable donations from their taxable incomes, and by 2011 individuals were claiming nearly $175 billion in charitable deductions.

Here we will describe how economists think about and do research on philanthropy, what economists know about charitable giving, and how public policy influences it (see also Andreoni and Payne, 2013). The focus will be primarily on gifts of money and assets by individuals, although corporations and other institutions also make charitable gifts (see Williams, 2003), and people also give by volunteering time (see Brown and Martin, 2012). In addition, the discussion will center on philanthropy in the United States, since a large majority of the academic research has centered on the American experience (for information on charitable organizations internationally, see Anheier and Kendall, 2001). Finally, we will highlight what challenges remain ahead for the study of philanthropy.

An Economist's View of Charitable Behavior

Economics is founded on the view that people are self-interested. Economists assume that since individuals have a choice in how they behave, they must always make the choices that they think are the best at the time. This assumption, called the 'axiom of rationality,' provides the bedrock from which economic models of behavior are formed.

Applying this framework to philanthropic behavior, we can ask why would someone who works hard for his or her money simply turn around and give it away? Does not this contradict the assumption that individuals are self-interested? Maybe. But by the axiom of rationality, we should first look for ways in which an individual believes that giving to charity is the best thing to do with that money at that time.

One possibility is that people desire more of the service provided by the charity. National Public Radio (NPR), for instance, is a charitable organization that survives largely on donations. Over a million people a year give to NPR with most giving under $100. Are these givers getting their money's worth? Certainly not. Anyone can listen to NPR broadcasts, even without donating, and anyone who gives $100 is unlikely to notice any increase in broadcast quality as a result. It follows that a self-interested person is better off giving nothing and taking a 'free ride' on the donations of others. Hence, this alone cannot be an adequate explanation for why people give to charity (Andreoni, 1988).

A second reason is that individuals may be getting something directly from the charity in exchange for their contributions. For instance, big donors may get better seats to the opera, or donors to a university may get buildings named for them. While this must surely matter for large donors, most individuals only receive tokens (a coffee mug?), if anything, in exchange for donations.

A third reason could be that individuals get some internal satisfaction – a 'warm-glow' – from giving to their favored charity, and the more they give, the better they feel (Andreoni, 1989). This would mean that giving to charity is like buying any other good, such as ice cream. We easily accept that people have a natural taste for ice cream, so why not a natural taste for warm-glow? If we accept this, then we can analyze charitable giving just like any other consumer good – when income goes up people should want more, and when the price goes up people should want less. Scholars have examined preferences

 http://dx.doi.org/10.1016/B978-0-08-097086-8.71001-4

for giving from a number of different approaches, and it seems that warm-glow is in fact a core economic motivation for giving (Andreoni, 1993; Ribar and Wilhelm, 2002; Harbaugh et al., 2007). But what is it that produces the private benefit from giving? Warm-glow could stem from religious duty, from pressure at work or from friends, as a signal of social status (Rose-Ackerman, 1996), or to project a positive image to others (Andreoni and Bernheim, 2009). At the heart of all of these processes, however, seems to be a basic human interest in helping others or doing one's share. So for this discussion, we will take as our launching point the idea that people get joy from giving and apply our economist's tools for analyzing consumer behavior to the study of charitable giving.

The Facts about Philanthropy in the United States

How do we learn about charitable giving? One source is surveys of consumers. The Center on Philanthropy, for instance, conducts regular surveys of over 8000 households. Surveys are valuable since they can obtain information on age, education levels, and other personal characteristics of respondents. A disadvantage is that individuals must rely on imprecise memories when answering questions, or may be reluctant to give true information about their incomes or donations.

A second important source is samples of tax returns. Since individuals who itemize their tax returns in the US can take a charitable deduction, we can learn about donations for this sector of the economy. The advantage to tax returns is that the information on them is precise, as long as people do not cheat on their taxes. (Slemrod (1989) explored this potential problem and found that, while there is some evidence of cheating by overstating charitable deductions, the effects are small and do not appreciably affect the analysis.) The disadvantage to this data is that tax returns contain very little information about the personal characteristics of the filers that would be helpful in explaining giving, such as education levels or religious affiliation, nor can we learn about the giving habits of those who do not itemize their tax returns. Since no data source is perfect, economists must conduct many studies on many data sources in order to uncover the 'facts' on charitable giving.

Sources, Totals, and Trends in Giving

Charitable donations can come from individuals, charitable foundations, corporations, or through bequests. While all are significant, by far the dominant source of giving is from individuals. Table 1 shows that in 2011 individuals gave over $217 billion to charity, or 73% of the total dollars donated. The second biggest source, foundations, was responsible for 14% of all donations.

Table 1 Sources of private philanthropy, 2011

Source of gifts	*Billions of dollars*	*Percent of total*
Individuals	217.8	73
Foundations	41.7	14
Bequests	24.4	8
Corporations	14.6	5
Total for all sources	298.5	100

Source: Giving USA, annual report 2012.

Figure 1 Giving by individuals, 1981–2011. Dollars are inflation-adjusted to 2011 values. Source: Giving USA, annual report 2012.

The trends in giving over the last 30 years can be seen in Figure 1. Total giving has been on a steady rise, with especially big jumps coming in 1996, 1997, and 1998. When measured as a percent of income, however, giving seems much more stable. Since 1968, giving has varied from 1.6 to 2.1% of the income. This figure has been remarkably stable for decades, with the occasional dips due to recessions or increases for special times of need.

Who Gives?

The Center on Philanthropy survey indicates that 65.6% of households gave to charity in 2009 and that the average gifts among those giving was $2313, exactly 2% of income. Table 2 shows that as household incomes rise, the household is more likely to give, and will make larger donations. This table also reveals an interesting pattern typically found in charitable statistics. Those with the lowest incomes tend to give the highest share of income to charity, in this survey it is 3.6% of income, while middle-income people give the least. For very high incomes, which are not captured by this data, giving again tends to swing up on average, although often with quite large differences in giving among the very rich (Auten et al., 2000).

What could cause this 'u-shaped' giving pattern? One explanation is that those with low incomes may be young people who know their wages will be rising, hence they feel they can afford more giving now. It may also be due to the types of charities people give to, since lower income people tend to give significantly more to religious causes. As we see, it will be important to account for all the factors that may explain giving before offering explanations for the averages seen in these tables.

Table 2 also illustrates that giving varies significantly with the age and educational attainment of the givers. As people get older, they are typically more likely to give to charity and to give a greater fraction of their incomes. Likewise, those with more education give more often, give more dollars, and generally give a higher fraction of income. Again, age, education, and income all vary with each grouping in the table and will have to be considered jointly.

Table 2 Private philanthropy by income, age, and education of the giver, 2009

	Percent of households who give	*Average amount given by those who give (in dollars)*	*Percent of household income*
All contributing households	65.6	2313	2.0
Household income			
Under $15,000	32.5	899	3.6
$15,000–$29,999	50.1	1219	2.7
$30,000–$44,999	53.5	1322	1.9
$45,000–$59,999	68.8	1608	2.1
$60,000–$74,999	73.3	1699	1.9
$75,000–$99,999	77.7	2298	2.1
$100,000–$124,999	87.9	2850	2.3
$125,000–$149,999	91.1	3277	2.2
$150,000–$200,000	94.4	3428	1.9
$200,000 and above	91.4	6989	1.8
Age of giver			
18–24 years	33.0	709	0.8
25–34 years	52.3	1385	1.2
35–44 years	61.4	1701	1.2
45–54 years	64.7	2692	1.9
55–64 years	76.3	2762	2.4
65–74 years	80.2	2785	3.3
75 years and above	80.3	2618	4.8
Highest education of giver			
Not a high school graduate	40.5	1209	1.2
High school graduate	57.0	1770	1.9
Some college	70.6	2122	1.2
College graduate or more	84.1	3145	2.3

What Do They Give To?

In 2009, over 320 000 charitable, religious, and other nonprofit organizations filed with the US government. Table 3 attempts to categorize these charities by the types of services they provide. This reveals that, among all types, households are most likely to give to religious organizations and to give them the most money – 41.9% of all households give to religion and 57.5% of all charitable dollars go to religion.

Table 3 Private philanthropy by type of charitable organization, 2009

Type of charity	*Percent of households who give*	*Average amount given by those who give (in dollars)*	*Percent of total household contributions*
Arts, culture, humanities	8.0	360	1.9
Combined	25.3	613	10.2
Education	14.5	544	5.2
Environment	9.2	215	1.3
Health	23.6	305	4.8
International	5.4	402	1.4
Need	31.5	549	11.4
Neighborhood	4.7	288	0.9
Religious	41.9	2086	57.5
Youth	12.0	247	2.0
Other	7.8	662	3.4

Taxes and Giving

How can taxes encourage philanthropic behavior? Taxpayers in the US who itemize their deductions can deduct their charitable giving from their taxable income. If someone in the 15% marginal tax bracket gives $100 to charity and takes a charitable deduction, this person will save $15 in taxes, making the net cost of the gift $85. If the person was in the 31% tax bracket then the $100 gift would have a net cost of $69. Thus, the higher one's tax rate, the lower the net cost of giving. In this way the tax rate acts as a subsidy rate to giving, and those in higher tax brackets get bigger subsidies. (Note that state income taxes often add additional subsidies. See Feenberg, 1987.)

Since the tax deduction subsidizes giving, we should expect that those with higher subsidies will make larger contributions. It is also natural to expect that those with higher incomes will make larger contributions. However, those with higher incomes will typically also have higher subsidies, so when we see richer people giving more how can we know whether their income or the subsidy is causing the change? If we can compare people with similar subsidy rates but different incomes, and similar incomes but different subsidy rates, we can apply statistical techniques to separate the influences of income and the subsidy.

Note that no one can give to charity solely to 'get a tax benefit.' Even a person in the highest federal tax bracket, 35%, will still pay 65 cents to give away another dollar. But this can skew how we view the statistics when we report giving as a percent of income. Earlier we noted that someone with income of $35 000 would give 1.9% of income, as would someone with income of $175 000. Since the marginal tax rate at the low income is 15% and at the high income is 35%, the higher income person is getting a bigger tax benefit. After the tax savings, the low earner's net contribution is 1.6% of income, while for the high earner it is 1.3%.

An important thing for policy makers to determine is whether subsidizing giving through tax deductions is worth the cost to the government. If, for instance, the subsidy does not increase giving at all, then the policy is costing the government tax dollars without benefiting the charities. If, on the other hand, the subsidy creates a dramatic response, tax deductions may be an effective tool to increase social well-being. Generally, policy makers look for the increase in contributions due to the subsidy (the benefit) to be larger than the loss in tax dollars (the cost). The next section discusses how economists explore this issue.

The Effect of the Subsidy on Giving

Economists began conducting detailed empirical studies of giving in the 1970s in an attempt to isolate the effect of the subsidy on giving (see Clotfelter, 1985, for a review). You can imagine asking the counterfactual policy question this way: Consider a proposal that would allow everyone to claim 110% of their current deduction on their income taxes – make a $100

contribution and take a deduction for $110. This means that the net cost of a $100 contribution would fall by 10%. For someone in the 28% marginal tax bracket, for instance, the cost of giving $100 would fall from $72 to $62.80. We would expect that this lower cost might encourage more giving, but by how much?

The first generation of studies to explore this counterfactual relied on cross-sectional data, primarily from tax returns. Observing income and deductions for thousands of people in a given tax year, the researchers use the variations in income and cost to estimate how, on average, individuals would respond to such a change in policy. There were several limiting features of the data used in these studies. Of particular importance is that the samples, for reasons of confidentiality, typically did not include extremely wealthy people.

Depending on the source of the data, the years studied, the size of the sample, and the statistical approach, the results naturally varied. It has been generally agreed, however, that the prediction that best characterizes the results is that a policy that would reduce the cost to donors by 10% – without affecting the other income taxes paid by the individual – would increase their contributions by about 13% (Clotfelter, 1990). This suggests that behavior is quite responsive to the incentives offered by the tax deduction, and that the response is large enough to satisfy the policy criterion noted above. In particular, if the government pays an additional 10% of the cost of giving and if people respond by giving 13% more, then the policy generates more new charity than it costs the government in tax revenue.

These studies also confirmed that giving increases with income. If after-tax incomes were to rise by 10%, estimates are that giving would rise by about 8% (Clotfelter, 1990). Notice that this quantifies the left-hand part of the u-shaped giving curve discussed in Section An Economist's View of Charitable Behavior – since giving rises by a lesser percent than income, giving as a percent of income (all else equal) must be declining.

Later studies were able to supplement these findings using data from surveys rather than tax returns (see Clotfelter, 1990; Steinberg, 1990). Although the survey results varied, they generally confirmed the policy predictions stated above. In addition, they revealed the importance of other individual characteristics in explaining giving. Most strikingly, they consistently found that giving increases with the age and the education of the giver, as suggested in the tables above. It could be that those who are educated have more interest in charity or that interest in charity changes with age. A more plausible explanation, however, is that researchers have no information on individual wealth, and since wealth is correlated with both age and education, it is likely that the influence of wealth is being filtered through these other variables.

A second generation of studies, conducted mostly in the 1990s, has begun to shift the consensus view noted above. Unlike the earlier studies that relied on cross-sectional data, these newer studies used panel data, that is, data with observations on the same set of individuals over several years. Panel data is generally seen as superior to cross-sectional data. The reason is that by observing the same people at different points in time, the researcher is able to get a more precise measure of how behavior responds to changes in the environment.

Randolph (1995) used tax returns on about 12 000 people from 1979 to 1988, and statistical techniques designed explicitly for panel data identified a much weaker effect of the subsidy and a much stronger effect of income. His results indicate that a policy that would increase the government subsidy by 10% would increase giving by only about 5%, whereas if income were to rise by 10% giving would rise by 11%. Others using panel data have found similar effects. Hence, at the end of the 1990s, the literature on the effect of the subsidy to giving was in a state of flux.

Bakija and Heim (2011) waded into these waters in an attempt to reconcile these differences. Like Randolph, they assembled a panel of tax returns, but their panel was much larger, with over 550 000 returns on almost 60 000 tax filing units. They also adopted an estimation technique that contained elements of the original analysis from the 1970s and 1980s as well as the more dynamic analysis of the 1990s. In addition, the data had a distinct advantage in having data on very wealthy households.

Their results were a mix of the two prior generations of findings. For households with incomes below $200 000, a 10% increase in the subsidy only raises giving by 7–8%. On these people, the government is getting less new charity than it is losing in revenue. For families reporting incomes of $200 000 on up to millionaires, Bakija and Heim predict that, on average, a 10% increase in the subsidy will raise giving by 11–13%, thus the government gets a good return on its investment from these donors. An important caveat to these results, however, is that while the prediction for low- to upper-middle-income households is fairly precise, estimates for the top 5% of incomes is very imprecise – the true response to a 10% increased subsidy could be anywhere from 5 to 20% increase in giving by the wealthy. While this article is a step forward, the literature is still inconclusive about the giving behavior of the very wealthy.

Do Government Grants Displace Private Philanthropy?

There are several reasons to suspect that government grants to charities might depress private donations. First, if givers are aware of the grants, then they may perceive the charity as less in need of their donations, leading them to keep the money or give it to a different cause. This is known as the 'crowding out' hypothesis (Warr, 1982; Roberts, 1984; Bergstrom et al.,1986). A second reason giving may decline is that the charity may be less aggressive in fundraising after receiving a government grant. Both effects would lead to government grants to offset private philanthropy.

There are also reasons to think that government grants could have the opposite effect. Citizens who are unsure about the quality of a charity could see a grant as a 'stamp of approval' (Andreoni et al., 2014). Or the grant could be used as 'seed money' that will allow the charity to expand into a bigger operation by, for instance, constructing new buildings or opening branches in different cities (Andreoni, 1998). In both of these cases, government grants could actually encourage private philanthropy.

An important difficulty in unraveling these effects is that the government and the voters are likely to have similar tastes. For instance, a tsunami may cause both individuals and the government to give more to that cause, but it would be incorrect to conclude that the government giving 'caused' the private giving – the tsunami caused them both simultaneously.

Failure to account for this 'simultaneity bias' would make it appear that crowding out is smaller than it appears.

This was pointed out in important study by Payne (1998). She used a 10-year panel of 430 US charities, and applied special statistical techniques to account for the fact that government grants to charities may be caused by the same needs and interests as private giving. While prior research that did not account for this found no crowding out, her analysis predicts about 50% crowding out.

Several years later, Andreoni and Payne (2003, 2011) discovered something important was missing from this research – charitable fundraising. Most charities find fundraising as a necessary distraction from their main mission, and a government grant gives them a reason to redirect their efforts back to the charity itself. That is, a grant may crowd out giving indirectly by causing the charities to cut back their efforts at fundraising.

Andreoni and Payne explore this possibility by analyzing tax filings of over 8000 charitable organizations in the US for up to 12 years. Looking at the congressional district the charity is located in, and including measures for how powerful their representative may be in helping secure grants in the district, they are able to map the simultaneity of government and private giving to the charity. They find that overall, a government grant of $10 000 reduces giving about $7500 – a substantial crowding out. However, a large fraction of this is due to a reduction in fundraising by the charity. Breaking it down, of the $7500 reduction in giving, from $5250 to all $7500 is due to the charity reducing fundraising after a grant. This points to the importance of understanding fundraising for making wise policy decisions.

Fundraising and Matching Grants

The last section highlighted how important fundraising is in understanding the effects of government policy. Often times, major donors to charity can affect the same kinds of policies used by the government. For instance, a single wealthy donor will sometimes give a large sum, which they then promise as 'matching gifts' to other donors. The wealthy philanthropist may promise to spend up to $1 million by giving $1 for every $1 raised from other donors. This is very similar to a government subsidy. What is the effect? Does it work as an effective subsidy to others' gifts?

Two papers looked at this issue, Karlan and List (2007) and Huck and Rasul (2011). There are several factors that make inference about matching gifts difficult. First, is it really a match? If the charity usually raises $5 million in a fund drive, then the donor expects to spend the entire $1 million, meaning that no one's donation really had an effect on whether $1 would be collected. In that case the matching gift is really more like a 'leadership gift' (Andreoni, 1998). Leadership gifts have importance often because they can signal the quality of the charity, or they can provide assurance that the charity's goals will be met. In both cases, the leadership gift can inspire others to give more, that is, they can 'crowd in' rather than crowd out smaller donors.

These two research studies conducted experiments with actual charities to try to determine which story fit the data. What they found was that individuals tended to respond to the fact of a matching gift, but not to the match level; a $1-for-$1 match raised as much as a $3-for-$1 match. But giving responded to a simple announcement of an equivalent leadership donation about the same as it did to an announcement of a matching gift. Thus, matching gifts work, but it is likely because they work like leadership gifts rather than that they act like subsidies to giving.

Conclusions and Future Research

Philanthropy is a significant factor in the US economy, accounting for about 2% of income almost every year for the past 40 years. Government and private givers are in a partnership to fund the services of almost 200 000 charitable organizations. This article has discussed the economic influences on private philanthropy and how it interacts with government policy.

The most important finding is that individuals are indeed sensitive to the charitable deduction in the US tax system. By subsidizing giving, the tax deduction has clearly increased giving by the private sector, although the effect clearly differs across income groups. The tax deduction is only available to those who itemize deductions on their tax returns, thus low-income individuals get no benefit. For middle-income people who itemize, the deduction returns 10–28% of their donation in lower taxes, and increases their donations by 7–20%. High-income households, making $200 000 per year and more get 33–35% of their donation back in lower taxes, and this raises their donations by about 35–40%.

The literature on the crowding out of private giving by government grants indicates that an important factor in the analysis is the role of fundraising. When charities get grants, many will redirect their efforts away from fundraising. As a result, government grants only result in about 30 cents on the dollar of new charitable services.

What can we look forward to as the important questions for future research? A surprising new development in the world of charitable giving is the explosion in private foundations. A foundation is a tax-exempt organization with a charitable or not-for-profit mission. Individuals, especially very wealthy individuals, have been setting up foundations at increasing rates. Part of this is to gain tax savings during life rather than to allow money to pass into an estate, but part is also a sincere desire to do good during one's life. Recent studies have indicated that foundations are increasingly important and powerful participants in the market for charity and deserve greater attention by researchers and policy makers.

Abstract

Charity and philanthropy are overlapping concepts whose habitual, periodic, and diverse expressions throughout recorded history across cultures and time have resulted in mainly positive benefits for humankind and societies. Formal research regarding the nature, history, extent, impact, and changing outlook concerning these twin concepts is a fairly recent development and has spawned a growing and ever more robust literature with many underexplored and still poorly understood dimensions.

Charity and philanthropy have been defined in different ways through the ages and in diverse cultures. Both concepts involve, in general, a basic desire to make a positive difference in the lives of others. Philanthropy literally conveys the idea of goodwill demonstrated toward the human race, while charity is an empathetic and altruistic response, frequently to human misfortune or suffering ('love in working clothes'). Both concepts involve a direct or indirect relationship between a personal giver (donor) and others within the realm of civic life, rather than relying solely on governmental or strictly institutional actions.

Philanthropy, according to a broad Western definition, is voluntary action for the public good, where 'voluntary' means unforced and free, where 'action' refers to giving, serving, and associating, and where 'public good' refers to creation of goods that are indivisible and nonexcludable or improve the quality of life for other(s) for whom one is not formally responsible. This improvement in the quality of life may include the alleviation of suffering by means of satisfying basic needs (e.g., food and shelter) and/or enhancing life by satisfying nonbasic needs (e.g., recreation, education, and self-actualization) (Payton and Moody, 2008). Traditionally, both the subject and object of philanthropy are humans or groups of humans, although in more recent centuries other creatures and the environment itself increasingly are objects of interest. Many other definitions of philanthropy and related terms exist, including diverse non-Western perspectives (Smith et al., 2006; Ilchman et al., 1998). This article focuses primarily on a Western perspective since the overwhelming bulk of research conducted to date has been undertaken in Western nations by researchers working within this broad cultural tradition.

Historical Meaning of Philanthropy

Philanthropy is an umbrella word used to describe a range of concepts from past to present and from academic to practical. Philanthropy originated in ancient Greece between the fifth and fourth centuries BC as a specialized philosophical and theological term to describe a facilitator of human advancement and was applied to an exceedingly wide range of human activities (Sulek, 2009a). One of the oldest documented philanthropic acts, more in keeping with modern usage, was the endowment of Plato's Academy where Plato picked his successor and bequeathed his wealth upon his death (347 BC). It lasted until Philo of Larissa's death in 83 BC, followed by a subsequent revival in AD 410, and final abolition of the Academy by order of Justinian I in AD 529 for a total duration of 383 years. Preliminary evidence from around the globe regarding the ancient world highlights charitable and philanthropic actions by rulers, their subjects, an various social organizations with religious texts from various traditions encouraging such behaviors and public and more private solicitations, formal petitions (from commoners and nobility alike), and commendations accompanying its practice (e.g., Veyne, 1992).

The meaning of philanthropy by the nineteenth century still referred to one of seven broad categories: literal, archaic, ideal, ontological, volitional, actual, and social (Sulek, 2009b). During the twentieth century, the term philanthropy became narrower in both scholarly discourse and public use, primarily referring to the act of giving and actions that follow from it.

Present-Day Paradigms of Giving

In current academic discourse, three paradigms of giving can be distinguished (Gunderman, 2008). The first one, egoistic giving, is described as a function of a donor's egoism. For example, in the fourth century BC, Spurius Maelius was slain for his philanthropic deeds, because he was suspected of trying to obtain political power. Since the Industrial Revolution, egoistic giving was viewed as a means of controlling the working class (Davis, 1999; Adam, 2009). During the Great Depression in the 1930s, egoistic giving served as 'riot insurance' for businessmen and bankers (Bremner, 1988). In the twentieth century, egoistic giving was pilloried as a means to socially repent for acquired wealth, build a legacy (Rosenwald, 2008), or feed one's pride (Menninger, 2008). Despite this critique, egoistic giving may be perceived as beneficial to society overall, if there is no such thing as 'bad' giving (Kelley, 2008) or a giver embodies some notion of the public interest (Kristol, 2008).

Compassionate giving or charity, the second paradigm of giving, is described as a model of philanthropy historically aiming to satisfy immediate human needs. In the United States, for example, formal expression of compassionate giving can be traced to Governor John Winthrop's 'A Model of Christian Charity,' composed in 1630. Within Judaic traditions, compassionate giving relates to the concepts of *Tzedakah* (works of charity, justice) and *Tikkun Olam* (repairing the world). In Christian traditions, compassionate giving relates to concepts of *caritas* (unlimited loving kindness to all others), *tithe* (literally a 'tenth' of one's income, drawing upon the Old Testament), and *offerings* given as part of Christian worship. In Muslim traditions, compassionate giving relates to concepts of *takaful* (social solidarity), *zakat* (donating a fraction of wealth as part of one's worship), *sadaqa* (benevolence), and *waqf* (endowments). Historical studies of these and other traditions as they relate to charity clearly demonstrate both strategic and far-sighted perspectives that informed giving and efforts to improve both communities and societies (e.g., Loewenberg, 2001 (ancient Judaism); Hamel, 1990 (Christianity and Judaism); Singer, 2008 (Islam); Constantelos, 1991, 1992 (Orthodoxy); Smith, 2009 (medieval China); and Ilchman et al., 1998 and Barnett and Stein, 2012 (current world religions)).

Scientific giving, the third paradigm of giving, aspires to improve systematically particular aspects of the human condition. For example, instead of focusing on feeding the hungry, scientific giving aims to make the hungry self-sufficient, so they can feed themselves. To achieve such far-reaching goals, scientific giving takes a long and wide perspective. It insists on rationalized giving and often aspires to objective measurable outcomes. Scientific giving is frequently presented as a novel approach and superior to compassionate giving, which, in both cases, is not correct (Schambra, 2008; Ruswick, 2013). While scientific giving has proved highly successful in some areas, most notably medicine, its overall effectiveness is not as obvious. In Western culture, the roots of scientific giving can be traced to the Enlightenment era, when philanthropy began to refer increasingly to rational consciousness. Recent examples of these approaches include strategic, performance, and outcomes philanthropy (Brest, 2012; CSR Asia, 2010), catalytic philanthropy (Kramer, 2009), venture philanthropy and social impact investing (where philanthropy focuses on maximizing socially valuable outcomes rather than strictly economic ones) (John, 2012; John et al., 2013), philanthrocapitalism (Bishop and Green, 2008), and similar conceptualizations. There are a number of hybrid concepts, which contain elements from the above paradigms or which relate to paradigms not classified as philanthropy (e.g., cause-related marketing).

While all three paradigms of giving can be found in nations around the globe, the mix and extent of them will vary depending on historical, sociopolitical, cultural, geographic, economic, and other factors. Western European nations, for example, considerably expanded the depth and breadth of the welfare state as working class movements, political parties, and formal organizations worked out varied approaches to provide social supports and safety nets as a matter of fundamental rights across the human lifespan (Kaufmann, 2012; Castles et al., 2010). A corollary to these fundamental changes in societal provision for housing, education, health care, and social services as entitlements was a correspondingly substantial rise in tax rates for many wage earners and a decrease in both the need for and provision of private charity and philanthropy. Yet, within these strong social welfare states there is considerable variation in private charitable giving and philanthropy with Swedes, for example, living in what is usually regarded as one of the most extensive social welfare regimes, giving at a rate considerably above the European average (Vamstad and von Essen, 2013). Despite the sometimes immense differences in both social welfare provision and charitable giving, the influence of tax incentives and price and income elasticities appears to differ very little, if several comparative studies of Germany and the United States are a reliable guide (e.g., Bönke et al., 2013).

Social Capital

Social capital is a concept closely linked to philanthropy. Social capital, in general, refers to the value of social relations that positively affect individual or collective productivity. There is no one single, universally accepted definition of social capital. Philanthropy both promotes social capital and relies on it. The term 'social capital' can be traced to a 1916 article on the rural school community center by Lyda Judson Hanifan. Wider academic use of the term began in the 1950s.

Current research identifies a number of positive and negative consequences of social capital. The positive consequences of social capital include better education and child welfare, safe and productive neighborhoods, better health, happiness, economic prosperity, and better democracy, social order, and social support. The negative consequences of social capital are related to excessive costs of membership (e.g., the costs of belonging to a social group may impose demanding norms of behavior), limited individual freedom (solidarity of a social group may restrict individual freedoms), downward leveling of norms (successful outliers may be exploited by their social group), exclusiveness (those outside social relations may be excluded from the benefits), and antagonism (those outside the group may resent the solidarity of the group) (Portes, 1998; Putnam, 2000).

Nonprofit Sector

The nonprofit sector, in general, refers to a sphere of private, formal economic activity without paying dividends or profits to owners or investors. Philanthropy is an important source of support for the nonprofit sector (e.g., Zunz, 2011; Bradley, 2009; Tennant, 2007). Philanthropy in a broader sense also includes activities carried out in the sector, for example, community building as a means of creating social capital (Salamon, 2010). A multitude of substitute terms exist to define nonprofit organizations across different geographical locations, legal systems, cultural traditions, and disciplinary perspectives (Lohmann, 1992). Four distinguishable concepts for the nonprofit sector can be delineated (Salamon and Anheier, 2006).

Charitable, nonprofit, and voluntary sector are terms that can be traced back to the Elizabethan Poor Law of 1601 in England. The US federal tax code has used the term 'nonprofit' since the 1950s to define these incorporations bound by a nondistribution constraint and also employs the term 'public

charity.' The concept also emphasizes a type of service that is defined by law as 'charitable' and includes services to the general public or to those in need, an orientation seen in the Statute of Charitable Uses in the United Kingdom and organizations that have proliferated in the United Kingdom (Hilton et al., 2012). Nonprofit is frequently critiqued for defining a sector by what it is not (Salamon and Anheier, 1996).

Social economy is a second concept that emphasizes the ethos of solidarity or ideology governing organizations within the nonprofit sector. The French term 'social economy' (économie sociale) can be traced to the beginning of the twentieth century. It is used to describe a sector comprising cooperatives, mutuals, associations (voluntary organizations), and foundations of public utility, which place service ahead of profit, place people and work ahead of capital, have autonomous management, and make decisions in a democratic manner. The term 'social enterprise' and the more recent term 'social business' carries this tradition around the globe, contextualized from place to place (Kerlin, 2009; Yunus and Weber, 2011).

Nongovernmental sector, independent sector, and third sector are terms referring to a third concept of the nonprofit sector that emphasizes sovereignty and specifically autonomy from the government. (The 'third sector' is everything that is not part of business or government. An older and less widely used term is the 'voluntary sector.') It focuses on the sector's function to empower the general public or those in need. As such, this concept is narrower than the other three uses and tends to be employed more frequently in emerging economies or post-socialistic countries (Salamon and Anheier, 1996).

Civil society is the term referring to a fourth concept of the nonprofit sector. This concept can be traced back to the 1980s when Central European states began their transition from socialism to democracy. This concept emphasizes the sovereignty of the sector in general with a focus on the noninstitutional, grassroots activity it conducts. This concept may incorporate suspicion toward organized institutions of the sector, which are sometimes believed to serve hidden agendas (Salamon and Anheier, 1996).

Given the conceptual diversity of the nonprofit sector, the Johns Hopkins Comparative Nonprofit Sector Project developed what was intended to be an internationally universal, structural/operational definition encompassing different legal and cultural traditions based on five key features (Salamon, 2010). The fundamental feature of the sector is that it consists of organizations. These organizations do not have to be formally constituted or legally registered but are characterized by structure and consistency in operations. The organizations are not part of government but may rely on public funding and may be private, not public. The primary purpose of the organizations is not commercial activity and they do not distribute profits to owners or managers. The organizations are self-governed, managed independently, control their own activities, and can independently decide to dissolve. The sector is voluntary and organizations do not impose membership or participation.

Theories of the Nonprofit Sector

The three-failures theory is the most widely employed idea to explain the existence of the nonprofit sector and the relationship among institutions of the public, private, and nonprofit sectors (Steinberg, 2006). Three-failures theory argues that the competitive market fails for three reasons. First, the market fails to supply pure public goods (i.e., goods consumed collectively and goods that do not diminish with additional consumption, e.g., national security). Second, the market fails to supply excludable goods to all who need them (i.e., some cannot afford even low-cost ones). Third, the market fails to supply the right quantity of certain private goods (i.e., goods that can be owned exclusively and customers can compete for them), a result of asymmetric information (Hansmann, 1980). Government could address these failures, because it does not operate to maximize profits, but it fails in two ways. First, government fails to provide goods that would satisfy the needs of minorities. Second, government fails to supply a sufficient quantity of collective goods to those with high levels of demand (Weisbrod, 1991). The nonprofit sector can address both market and government failures because it does not operate to maximize profits and it is not restricted to render a homogeneous response to heterogeneous demand as required by democratic principles. However, the nonprofit sector fails to offer an adequate supply of public goods, due to particularism, paternalism, philanthropic insufficiency, and amateurism (Salamon, 1987). This failure, in turn, is addressed by the private for-profit market and government sectors.

Giving in the United States of America

The most complete data sources on charitable giving can be found in the United States, partly because of long-standing federal tax authority rules that require annual disclosure of financial and operational details by nonprofits including lists of grants made and to whom; income received and sources of major income; salaries of the five highest paid staff, chief executive officer, and board members; contracts to third parties; investments; and subsidiary organizations. Individual tax payers as well as corporations may also file federal tax forms to claim various qualifying deductions, including those for charitable contributions. These two annual, comprehensive, and generally reliable sources of data can be used to understand giving across the nation.

Giving USA is the most comprehensive annual report about charitable giving. It has been published since 1956 by the Giving USA Foundation and researched and written by the Indiana University Lilly Family School of Philanthropy. *Giving USA* estimates are mostly based on econometric methods using tax data, government estimates for economic indicators, and information from other research institutions. The estimates are revised 2 years after their first publication when tax return information about itemized deductions by individuals and corporations and tax statements from nonprofit organizations (including foundations) become available. *Giving USA 2013* on giving for the year 2012 reports charitable giving amounting to $316.23 billion or 1.9% of the gross domestic product (GDP) (Giving USA Foundation, 2013). In comparison, over the last 40 years, total giving ranged from 1.7% of GDP to 2.3%. Total giving increased in current dollars every year but three (1987, 2008, and 2009) since recording began in 1956. In 2012, the largest source of contributions was individual giving

at $228.93 billion or 72% of total contributions. The other sources included giving by foundations ($45.74 billion or 15%), giving by bequests ($23.41 billion or 7%), and giving by corporations ($18.15 billion or 6%). Since the beginning of the study, the religious subsector has received the largest share of contributions. In 2012, giving to religion was estimated at $101.54 billion or 32% of total giving. However, giving to religious organizations has been decreasing as a share of the total giving since the 1986–90 period. The other major uses of giving include education ($41.33 billion or 13%); human services – response for those affected by the economic crisis, especially by providing emergency basic needs services ($40.40 billion or 13%); gifts to grant making foundations ($30.58 billion or 10%); health ($28.12 billion or 9%); gifts to public-society benefit funds, such as United Ways, Jewish Federations, and freestanding donor-advised funds ($21.63 billion or 7%); international affairs ($19.11 billion or 6%); arts, culture, and the humanities ($13.28 billion or 5%); and environment/animals ($8.30 billion or 3%). Besides monetary and in-kind gifts, *Giving USA* incorporates estimates on volunteering and the number of nonprofit organizations. According to the Corporation for National and Community Service, 64.3 million adults volunteered in 2011. At an estimated average value of volunteer work of $22.14 per volunteer hour, this amounts to $171 billion worth of volunteering in 2011. The number of tax-exempt organizations was estimated at 1 081 891.

The 2012 Bank of America Study of High Net Worth (HNW) Philanthropy is a leading resource on HNW individuals. It is a biannual study conducted by the Indiana University Lilly Family School of Philanthropy. The study is based on a random sample of US residents with a household income greater than $200 000 and/or net worth (excluding the value of their primary residence) of at least $1 000 000. The importance of research focusing specifically on HNW households derives from the reliance for nonprofit sector growth on the income volatility of the top income group (Parker and Vissing-Jorgensen, 2009), which raises concerns about rich households' ability to consistently finance the nonprofit sector. According to the fourth study, published in 2012 on giving in 2010, HNW households remained committed to supporting nonprofits despite the economic downturn, as 95.4% of those households donated to charity, as compared to 65.4% of the general population (Indiana University Lilly Family School of Philanthropy, 2012). Nearly 69% of wealthy households gave consistently year after year to the same organizations or causes. However, average charitable giving decreased by 6.8% from 2009 to 2011. The structure of giving by wealthy households differs from the structure of giving by the general population. In 2011, the most popular causes among HNW households were education (79.6%), basic needs (79.3%), art (68.8%), health (65.3%), and religion (65.2%). In 2011, 61% of HNW households gave their largest gift to fund the general operations of an organization, an increase of about 5% points from 2009 and likely in response to the increased difficulties organizations faced raising core operating expenses in a downturned economy. The study also found that HNW households tend to give strategically and are less willing to take risks in philanthropy than they are with their personal investment portfolio. The study also estimated volunteering. In 2011, 88.5% of HNW households volunteered. More than one-third of these volunteers gave 200 h or more of their time in 2011.

Giving in Global Perspective

A growing body of research informs the understanding of philanthropy, civil society, and the nonprofit sector in global perspective (e.g., Salamon and Anheier, 2006). This research is difficult for a number of reasons, including differences in the concept of philanthropy on cultural and legal levels, differences in the amount and quality of data available, risk of double counting, differences in purchasing power parity, and the scale and expense of a global study.

The Johns Hopkins Comparative Nonprofit Sector Project is a large-scale collaborative research project undertaken in some 40 countries beginning in the 1990s that generated for the first time a systematic body of global comparative data on the nonprofit sector. It is based on evidence from more than 600 nonprofits and other entities as well as secondary data that formed reasonably representative samples within the nations studied. In regards to the overall size of the nonprofit sector, the study estimates that in 35 countries, the nonprofit sector accounted for a total of 39.5 million full-time workers or an average of 4.4% of the economically active population in these countries. Such size would make it the seventh largest economy in the world, if all nonprofit sectors globally were a single country. The size of the sector varies considerably between countries, from 0.4% of the economically active population of Mexico to 14% in the Netherlands. The United States has the fourth largest nonprofit sector at 9.8% of the economically active population. There is also variation between developed countries and developing ones, but, on average, the nonprofit workforce in developed countries is over four times larger than in developing nations. In regards to the composition of the sector, the study found that 64% of nonprofit activities are carried out in service fields, comprising mainly education (23% of the workforce), social services (19%), health (14%), and development (8%). The bulk of remaining activities are carried out in expressive fields comprising mainly culture and recreation (19%), professional and business representation (7%), as well as civic advocacy and environmental protection (6%). With regards to volunteer inputs, the study found that 16.8 million or over 40% of full-time equivalent nonprofit workers in the analyzed 35 countries were volunteers. However, countries vary considerably in their reliance on volunteering as opposed to paid labor. For example, in Sweden, over 5% of the economically active population volunteered and less than 3% received pay for their work in the sector. On the other end (Belgium), less than 3% volunteered and over 8% received pay. These differences among countries were explained by cultural variations in the concept of volunteering. The study found that in Anglo-Saxon countries the concept of volunteering is rooted in the democratic concept of a self-organizing society, separate from business and the state. In other Western countries, such as Germany, the concept of volunteering is rooted in the autocratic concept of communal service for the public good. In some non-Western countries,

there is no tradition of volunteering and, therefore, its conceptualization is not well developed (for a recent view from Asia see Brassard et al., 2010). Regarding the revenue structure, the study found that in 32 analyzed nations, on average, 53% of all revenue came from fees, 35% came in the form of government funding, and 12% came from philanthropy. When the value of volunteer work is considered as a form of philanthropic support, philanthropy constituted 30% of total revenue. As in other cases, the structure of revenues in the nonprofit sector varied significantly between countries. Traditionally, government support is the most important source of funding for the nonprofit sector in Western Europe, while fees play a dominant role in the nonprofit sectors of countries in Africa, Central and Eastern Europe, Latin America, as well as in Australia, the United States, and Japan.

The Civil Society Organization Index is a composite index of civil society development used in the Johns Hopkins Comparative Nonprofit Sector. The index comprises three dimensions (capacity, sustainability, and impact) where each dimension is constructed on a number of different measures. The capacity dimension measures the employment level, the diversification of employment, mobilization of volunteers, and stimulation of charitable resources in the nonprofit sector. The sustainability dimension measures the financial base, membership, volunteering, and the supportiveness of the legal environment in which the nonprofit sector operates. The impact dimension measures the service function and expressive function of the nonprofit sector. The country scoring the highest in the index was the Netherlands with the highest scores in all three dimensions. The United States was third on the list and Mexico received the lowest score.

The World Giving Index (WGI) is based on data from the *Gallup WorldView World Poll*, an ongoing research project carried out in up to 153 countries involving over 150 000 people in its now annual stratified samples. The WGI is based upon three charitable behaviors: giving money to an organization, volunteering time in an organization, and helping a stranger. According to data collected in 2011 from 146 nations, societies give in different ways (Charities Aid Foundation, 2012). The frequency of giving money ranges from as low as 3% in Georgia and Senegal to 79% in Ireland. The frequency of volunteering ranges from 3% in Greece and Serbia to 58% in Turkmenistan. Helping strangers is the main way that the world gives as 45% of the world's population helped a stranger at least once in 2011. Based on the WGI aggregate value, around half of the 20 most charitable countries are wealthy nations, but around half are not (e.g., Liberia, Philippines, Sri Lanka, and Turkmenistan). The top 10 nations for overall giving (all three forms combined) in descending order were Australia, Ireland, Canada, New Zealand, the United States, the Netherlands, Indonesia, the United Kingdom, Paraguay, and Denmark. According to a 5-year trend analysis (Charities Aid Foundation, 2012), giving money is the highest among the oldest age groups, volunteering attracts the 35- to 49-year and 15- to 24-year age groups the most, while helping strangers is least common among those 50+.

The Index of Global Philanthropy and Remittances is an annual metastudy, which combines findings from multiple sources in different countries (Adelman et al., 2012). The data on remittances are derived from the World Bank's bilateral matrix, which is considered the only comprehensive and comparable source of all bilateral remittance flows between the Organization for Economic Cooperation and Development (OECD) and recipient countries. According to the 2012 publication on results from 2010, global philanthropy, remittances, and private capital investment worldwide totaled $575 billion or 82% of the developed world's economic dealings with developing countries. In this amount, government aid accounted for only 18% of total financial flows. The remittances from all Development Assistance Committee (DAC) donors within the OECD to developing nations were $190 billion. Among these donor countries, the United States was the biggest donor in terms of total assistance to developing countries at $165.2 billion (remittances, philanthropy, and private capital investments), but ranked 12th in terms of assistance as a percentage of gross national income (GNI) at 1.13%. On the recipient side, the largest receivers were India, China, and Mexico. The development of new funding mechanisms and technologies leads to increasingly blurred lines among remittances, philanthropy, and private capital investment, since varied percentages of these types of financing provide at least some direct or indirect charitable or philanthropic support to both individuals and households. Government support from the now 24 OECD nations that comprise the DAC generally fail to meet the United Nations Official Development Assistance Target of 0.7% of GNI per participating nation as only Sweden, Norway, Luxembourg, Denmark, and the Netherlands meet or slightly exceed this figure. The United States despite being the largest giver at $30.46 billion of direct government aid is sixth from the bottom in terms of percentage of GNI (Organization for Economic Cooperation and Development, 2013).

Emerging Trends in Philanthropy Research

Interest in research and education on charity and philanthropy is growing globally with active centers for research throughout Europe, Australia, New Zealand, and North America as well as emerging sites in Asia, Africa, Central and South America, and the Pacific. The Nonprofit Academic Centers Council serves as a voluntary federation of many of these centers. Research in charity and philanthropy is supported by private banks, corporations, government agencies, international agencies, private and public foundations, nonprofits, and individuals (e.g., Barclays Wealth, 2010 (global study); Budani, et al., 2010 (Latin America); Morris et al., 2011 and Mahmood and Santos, 2011 (Asia); Sheth and Singhal, 2011 (India); Fauzia, 2013 (Indonesia); Harrow et al., 2014 (global perspective from principally European researchers)). Large repositories of information regarding charity and philanthropy can be found in organizations such as the Foundation Center (New York City); Indiana University Lilly Family School of Philanthropy; the Council on Foundations (USA); the World Initiatives for Grantmaker Support, Inc. (WINGS, Brazil); and the European Foundation Centre (EFC, Brussels). Organizations like these serve as key connectors among researchers, research networks, data sources, practitioners, corporations, governments, foundations, and other organizations. The expansion of these

networks over the past decade in particular has prompted large-scale comparative work and many smaller comparative research projects.

Undergraduate and especially graduate degree programs up through the level of PhD specializing in charity and philanthropy can be found in many universities, often in different departments and with variable rigor. Annual academic conferences specializing in this arena include the meetings of the International Society for Third Sector Research, Association for Research on Nonprofit Organizations and Voluntary Action, Voluntary Action History Society, and the EMES European Research Network. A study of academic publishing trends in philanthropic studies concluded that the field is both growing and maturing in terms of the depth and breadth of the questions being asked and the amount and complexity of research undertaken (Graddy et al., 2011; cf Bekkers and Wiepking, 2011; Oppenheimer and Olivola, 2010). Due to the inherent multidisciplinary nature of charity and philanthropic research, literature is published by scholars around the globe in a huge variety of disciplines and specialties, particularly in business (chiefly management and organizational behavior), social work, sociology, psychology, history, economics, law, political science, religious studies, public policy studies, evaluation, and development studies. The lack of a comprehensive system of nomenclature can make locating all relevant research regarding the sector quite challenging.

This article is reproduced from the previous edition, volume 3, pp. 1659–1663, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

Metallurgy, ceramics, and pharmacy are ancient chemical technologies, but chemical science developed in the West from the seventeenth century. Antoine Lavoisier in the late eighteenth century, describing his work as revolutionary, introduced new language and new theory; and its exciting links to electricity made chemistry the fundamental science of the early nineteenth century. By mid-century, graduate schools like Justus Liebig's journals, institutes, and connections with industry had inaugurated professional chemistry. Its first major international conference, settling formulae, was held in 1860; by then crude vitalism had been abandoned, and chemistry was separating into specialisms (inorganic, organic, and physical) and subspecialisms. From about 1900, chemistry has been perceived as reduced to physics, a service science rather than a fundamental one; and its achievements in fertilizers, pesticides, explosives, and drugs are looked at askance. But chemists are ubiquitous, essential in scientific teamwork; and the creation of new molecules unknown in nature has gone on apace. The history of chemistry used to be written by practitioners interested in finding the roots of modern ideas, but has been largely taken over by historians more interested in contexts.

Introduction

The chemical sciences are concerned with specific kinds of matter and their transformations. Chemistry is very ancient, going back into remote prehistory with cookery, the preparation of drugs and dyes, the baking of clay into ceramics, and metalworking. Its evolution into a science, where theory guides practice, and into a profession, with formal courses and qualifications, happened in the eighteenth and nineteenth centuries (Brock, 1992). The boundaries of chemistry, notably with physics and biology, are social constructions that have varied in different times and places, especially in recent decades.

Ancient Technologies

From very remote times, people have been using techniques and processes that we would call chemical, involving careful control as part of a craft or art passed from father to son, mother to daughter, or master to apprentice. Indeed, the word 'chemistry' is supposed to have come from an ancient Egyptian word *chem* meaning earthy: the Arabic definite article *Al* was added to yield our 'alchemy,' and dropped to give *chymistry* and then by 1700, 'chemistry.' Early technologies, culminating in triumphs such as the making of porcelain and Japanese swords, include features we would regard as magical; but since the course of chemical reactions depends upon the purity of components, those involving natural products are hard to predict and to repeat. Recourse to prayers, incantations, and curious additives should not amaze us.

Metallurgy, Alchemy, and Pharmacy

Alchemy, with its objective of converting base metals into gold, which chemist–historians portrayed as absurd or dishonest, was not unreasonable. Nature was believed to be perfecting metals within her womb, and the alchemist was simply speeding up the process. If everything was composed, as Aristotle believed, of the four elements earth, water, air, and fire in different proportions, then changing these ratios would transform one substance into another, so that lead might become gold. If, alternatively, Democritus and Epicurus were correct in believing that in appearance there were colors, smells, and tastes, but in reality atoms and void; then because lead, gold, and everything is made up of different arrangements of these ultimately similar atoms (or 'corpuscles'), again conversions should be possible.

Alchemy began in Egypt and Babylonia, and also in China: with emphasis both upon making gold (or maybe something resembling it) using an elixir to expedite the process, and of prolonging and enhancing life by giving humans the noble and permanent qualities of gold. Pharmacy grew out of trial and error, but in the West the maverick Swiss doctor calling himself Paracelsus (1493–1541) brought alchemy into it. He introduced metallic compounds into previously herbal medicine, notably for the treatment of the new disease, syphilis, which was ravaging Europe. He publicly burnt the books of the great Greek physician, Galen, and saw chemical study as essential for medicine. His career outraged the medical establishment, but the powerful and dangerous new remedies proved irresistible to doctors and patients, and medical schools became centers for chemistry.

The First Chemical Theories

Until the mid-twentieth century, it was believed that alchemy was abandoned by the rational thinkers of the Scientific Revolution; especially Robert Boyle (1627–91) and Isaac Newton (1642–1727). Close examination of their manuscripts (Principe, 1998) shows that both of them were in fact adepts, copying out and trying alchemical recipes, and believing that they were well on the way to a transmutation. But they were also adherents to the atomic view of matter, seeing hard and indestructible corpuscles or particles as fundamental. These

formed very stable primary mixts, such as iron, gold, or sulfur, which in turn combined with each other. Unlike gravity, which was universal, chemical affinity was elective: some substances reacted together, others did not. J.W. Goethe wrote a novel, *Elective Affinities* (1809) exploring chemical and human bonding; chemists in eighteenth-century Germany and Sweden (the center of chemical activity) drew up tables of affinity in attempting to predict the outcome of reactions.

From Germany also came the first chemical paradigm. G.H. Stahl (1660–1734) proposed that everything, which would burn contained *phlogiston* (Greek, flammable): this idea brought order into chemical understanding, whereas atomic ideas were vague and untestable. Moreover, in Germany, Lorenz Croll in 1778 began the first chemical journal, *Chemische Annalen*, bringing into being a chemical community there (Hufbauer, 1982). His example was followed in France and England by Antoine Lavoisier and William Nicholson.

Lavoisier's Revolution

Lavoisier (1743–94) was a wealthy man, prominent in the privatized tax system of France; his spare time he devoted to chemistry, in a splendidly equipped laboratory. Becoming a member of the Royal Academy of Sciences, the small salaried body charged with scientific research, he resolved to reform the language and theory of chemistry. As in Carl Linnaeus' botany, names should be international, clear, and free from changeable theory: while *phlogiston* should be replaced as incoherent. Stahl saw *phlogiston* emitted in burning; Lavoisier by contrast (in a classic paradigm shift) saw something absorbed from the air, leading to an increase in weight. He drew upon the work of Joseph Priestley (1733–1804), who had isolated 'vital' or 'eminently respirable' air in a British tradition of work on gases. Lavoisier christened this substance 'oxygen' (Greek, sour) because he believed that it was also responsible for acidity (generalizing from analyses of nitric and sulfuric acids). Water was a compound of oxygen with another gas, hydrogen: such elements were the basis of chemistry, rather than the hypothetical corpuscles which might concern physicists, or the earth, water, air, and fire with which Priestley's friend Thomas Jefferson (1743–1826) structured his book on Virginia. In 1794, during Robespierre's Reign of Terror, Lavoisier was executed as a tax profiteer, while the left-wing views of Priestley (who continued to disagree with him over *phlogiston*) led to his exile in Pennsylvania. But their new and exciting chemistry survived and prospered (Bensaude-Vincent and Abbri, 1995; Knight and Kragh, 1998).

Electricity and Chemistry

In 1799, Alessandro Volta (1745–1827) showed that electricity was generated when two metals were dipped into water; there was no need for any animal tissue, as Luigi Galvani (1737–98) had supposed. His paper was an alarm bell, as Humphry Davy (1778–1829) put it, and chemists everywhere repeated and extended the experiments. But results were confusing until in 1806 Davy did the careful experiments confirming his intuition that pure water is decomposed electrically into oxygen and hydrogen only. Just as Newton had found that gravity was the force behind planetary motions, so Davy inferred that electricity and chemical affinity were manifestations of one power. In 1807, he used this insight in isolating the light and reactive metals potassium and sodium, and (putting Britain back on the chemical map) went on to demonstrate, with chlorine, that Lavoisier had been wrong about acidity.

Davy had been appointed to the newly founded Royal Institution in London's fashionable West End, where he proved himself to be an enormously popular lecturer, making professing a performance art (Golinski, 1992; Knight, 1998). The fees that men and women paid to join the Royal Institution, and hear Davy lecture, supported a research laboratory in the basement. Davy became one of the first people in Britain to make a living out of chemical research, which had previously perforce been a hobby for an aristocrat like Boyle, a minister of religion like Priestley, or a doctor like Galvani. At the Royal Institution, Davy trained (in a kind of informal apprenticeship) his successor, Michael Faraday (1791–1867), and the pursuit of Davy's insight that chemical affinity was electrical continued there.

With Lavoisier, chemistry had acquired an exact language, closer to algebra than to the evocative terms of the alchemists; and it included testable theories, for example, of acidity. It was the science of the secondary qualities – of colors, smells, and tastes – and it promised to be useful (chlorine for disinfecting and bleaching, for example, and oxygen for chest complaints). It also is proved popular everywhere. With its connection to electricity, it became the dynamic fundamental science, concerned not just with matter but also with force; there was as yet no unified science of physics. Mechanical explanations seemed shallow, while chemistry's connections with heat, light, and electricity went deep.

A Mature Science

J.J. Berzelius (1779–1848) in Sweden used the unsystematic Davy's insight to create a structure for chemistry: 'dualism' based on the idea that every compound had a positive and a negative part. He also picked up John Dalton's idea that each element was composed of identical atoms that differed from those of other elements: Berzelius arranged these in an electrochemical series from oxygen, the most negative, to potassium. The number of elements known steadily grew through the century with improvements in chemical analysis.

Berzelius trained a number of chemists by having them to stay in his house, where Anna the housekeeper washed up dishes and flasks. But in the 1820s, Justus Liebig (1803–73) at the University of Giessen launched the first graduate school for turning out a stream of chemists with PhD degrees (Brock, 1997; Morrell, 1997). Liebig's success depended upon his having perfected apparatus for analyzing organic compounds; his students usually did their research on some natural product, and published it in the journal that became called *Liebigs Annalen* after its editor. They found jobs, particularly in the dye industry (Fox and Nieto-Galan, 1999) and in pharmacy, both of which were becoming based in science rather than craft skills; many went to England, a rich country with a poor educational system. With the collapse of Napoleon's empire in

1815, the University of Berlin had emerged dedicated to research and teaching (*Wissenschaft und Bildung*), and the various German states began to compete in their opera houses and universities. They followed Giessen, building better laboratories and bidding for star chemists. Schools began teaching chemistry, textbooks were needed (Lundgren and Bensaude-Vincent, 2000), and academic careers opened up in a field now largely separated from medicine. Universities in Britain and the USA followed the German model, usually demanding German research experience from professorial candidates.

In the 1850s, chemists could agree about what things were made of, but not about formulae. Dalton had supposed that water must have the simplest possible formula, HO; Davy and others, notably Amadeo Avogadro (1776–1856), opted for the H_2O formula because two volumes of hydrogen combine with one of oxygen. An atom of oxygen thus weighed either 8 or 16 times as much as one of hydrogen, and such uncertainties ran through the whole list of elements. In 1860, August Kekule (1829–96), a pioneer in working out chemical structures such as that of benzene, called for an end to this confusion through an international conference, which met in Karlsruhe. It was poorly organized, but afterward chemists came to accept the reformulation of Avogadro's arguments by Stanislao Cannizzaro (1826–1910). With agreed atomic weights, tabular arrangement of the elements became possible; and the most successful was the periodic table of Dmitri Mendeleev (1834–1907).

Mendeleev's predictions of the properties of some hitherto undiscovered elements were startlingly accurate; and with the table (as he hoped) the student had to remember fewer brute facts. From its position in the table an element's properties could be known. It is striking that so many bright ideas, from Dalton via Cannizzaro to Mendeleev, came from people on the periphery rather than in the great scientific centers.

The Fragmentation of Chemistry

In death, we rot: for we (and animals and plants) are then subject to chemical reactions that go differently than while we are alive. Most people believed in a vital force that maintained life. It is claimed that Friedrich Woehler (1800–82), pupil of Berzelius and friend of Liebig, destroyed this vitalism when in 1828 he synthesized urea. In fact, the chief interest in this reaction was that ammonium cyanate and urea turned out to have the same atomic constitution: their different properties were the result of different arrangements (Brooke, 1995). So the story has more to do with understanding molecular structure; but the synthesis, and the work of Liebig and his students in analysis, showed that no gulf separated organic and inorganic worlds. Nevertheless, by 1848, when Berzelius died, it was clear that dualism did not fit organic compounds well, and as the chemical community grew it was convenient to separate organic chemistry, based upon carbon, from the inorganic branch. The expansion of universities led to new professorships and laboratories devoted to the specialism of organic chemistry, from which in the twentieth century emerged biochemistry.

Chemists had relied upon balances, test tubes, condensers, blowpipes, and other items of apparatus that were difficult to manipulate. The chemist had to think with his (or occasionally her) fingers and was proud of skills in glassblowing. Chemistry was essentially experimental, exciting, attractive, and often dangerous. Then in 1860, came collaboration between Robert Bunsen, inventor of the controllable gas burner, and the physicist G.R. Kirchhoff, who found that elements heated at a high temperature have characteristic spectra. Analysis could be done by physical methods, and this optical spectroscopy was the first of what is now an armory of such techniques that has transformed the appearance of chemical laboratories (Morris and Travis, 1997: pp. 715–740).

At about the same time, the new science of thermodynamics, based on energy and its transformations, brought together into classical physics sciences which had been separate or had been part of the empire of chemistry. Davy and Faraday had been pioneers in what became a new specialism, physical chemistry, investigating energy changes in reactions, and the mechanisms, rates, and reversibility of processes. The leaders here were Wilhelm Ostwald (1853–1932) and J.H. Van't Hoff (1852–1911) who launched a journal and promoted academic positions and laboratories. The new profession of chemical engineering was closely linked to the rise of physical chemistry. Whereas, early in the nineteenth century, chemists had been called in only as consultants or troubleshooters when something went wrong, by the end of the century they were employed full time (Bud and Roberts, 1984). In industry, intellectual property belongs generally to the company and not the individual, and is secured by patents (Travis et al., 1998).

The Reduction of Chemistry

The nineteenth century was the heyday of chemistry, the golden age in which it came to maturity and seemed fundamental. The chemist and spectroscopist William Crookes (1832–1919) followed Faraday in studying cathode rays, but J.J. Thomson in 1897 identified them as composed of subatomic corpuscles, soon named 'electrons.' The subsequent nuclear atomic model of Ernest Rutherford (1871–1937) – for whom all science was physics or stamp collecting – and Niels Bohr (1885–1962) accounted not only for spectra, but also for the periodic table. Chemistry became a branch of physics (Nye, 1996); the properties of gold could in principle be calculated from data about protons, neutrons, and electrons, though in practice the chemistry laboratory is essential. This meant that chemistry lost its glamor; the chemist was as ubiquitous as ever, an essential member of the teams or groups so characteristic of twentieth-century science, but playing a service role (Knight, 1995).

The number of chemists has continued to grow, as has the number of new substances they have synthesized that had been unknown in nature. Davy wrote of the chemist being a godlike creator, and this creativity is nowadays celebrated by chemists such as Roald Hoffmann. The engineer or architect must remember the law of gravity, but to mourn that architecture has been reduced to physics would be absurd: like the poet or the painter, the chemist has to work within constraints, but that is a feature of life – indeed making creativity possible (Hoffmann and Torrance, 1993).

Hoffmann, born in Poland, surviving World War II, escaping to the USA, learning chemistry there, and doing

research that brought him a Nobel Prize in 1981, exemplifies another trend. Chemistry reached the West via Islam. In the eighteenth and nineteenth centuries, it was a European science, with Germany the most important center by 1900. Papers in German journals, and research experience in Germany, counted high in any pecking order; but already the USA was becoming a major power in science. There in 1916, G.N. Lewis proposed the electronic theory of chemical combination, much developed by his pupil Linus Pauling. Since 1945, the USA has been the center of things, making the English language and publication in US journals the key to prestige in research. Two World Wars, and Hitler's coming to power between them, are part of the reason for this; equally important has been American prosperity, itself dependent on science. Chemistry has steadily gone West.

The Status of Chemistry

Davy and Liebig (Rossiter, 1975) wrote famous books on agricultural chemistry, and in the nineteenth century, chemical fertilizers and pesticides were unequivocally welcomed in a Europe of food shortages. Lavoisier improved French gunpowder, and later chemists produced high explosives making possible engineering achievements and also formidable weapons. All these things were seen as benefits. National chemical societies, their academic and professional aspects sometimes in tension, were formed and enjoyed prestige (Russell et al., 1977). Although pollution from new chemical industries (as from older ones like tanning) was palpable and led to legislation, the expectation was that the chemists would be able to cure it. It did not happen: Rachel Carson's book *The Silent Spring* (1962) alerted the world to the dangers. So in the late twentieth century, despite successes such as plastics, and the array of new drugs available for medicine, chemistry is seen as boring and its applications as threatening. Chemists feel misunderstood and underappreciated.

Twentieth-century chemistry is dominated not only by universities in the Giessen tradition, but also by big-spending international companies with research laboratories, now turning toward biotechnology (Galambos and Sturchio, 1997; Kevles, 1997) and by the military. Research is carried on no longer by a Woehler or a Crookes, on their own or with assistants, but by teams of people possessing various skills. Chemistry has been taught in an impersonal way, with less hands-on experiment in a world more conscious of health and safety.

This is a strange eventful history, which until the mid-twentieth century was mainly written by participants who looked for progress. They had the advantage of being familiar with chemicals and apparatus, but professional historians of science have come to look more closely at contexts and careers. The history that emerges deserves to be known beyond the world of chemists.

Editor's Note

The history of the chemical sciences continues to converge with the histories of other fields, and not only through links with other traditional disciplines, such as physics and biology. Chemistry also is being folded into broad international initiatives that involve large public expenditures as well as efforts to attract commercial interest and capital. These initiatives include biotechnology and genomics, synthetic biology, nanotechnology and molecular electronics. Science, technology, and medicine are more closely integrated than ever, and major chemical companies such as Dupont and Monsanto have expanded into agricultural and medical biotechnology, and not without courting plenty of controversy. Recent research in science and technology reflects this trend. Historians of science continue to write about the chemical revolution, but sociological, anthropological and other studies of contemporary chemistry are pursuing chemistry through a thicket of initiatives involving multiple fields and corporate-university relations.

Recent studies on the history of chemistry include Ursula Klein and Wolfgang Lefèvre (2007), Lissa Roberts and Rina Knoeff (2007). For studies on the recent era of multidisciplinary initiatives and entrepreneurial research see: Steven Shapin (2008), Stephen Hilgartner (2012).

Abstract

Developed as a cross-culturally comparative concept within early to mid-twentieth century cultural evolutionary anthropology and processual archaeology, chiefdoms are defined as smaller scale complex societies that are sometimes intermediate to state development, with centralized decision-making hierarchies, some degree of hereditary social ranking, and economic centralization. In historically and ethnographically known chiefdoms, chiefs generally construct and maintain political power bases through various economic means (tribute collection, control over production and exchange, foreign trade monopolies), ideological means (ritual, myth, sacred landscapes), and military coercion. Archaeologists have recognized that these power strategies are materialized archaeologically in a variety of highly visible ways (such as monumental construction, settlement hierarchies, specialized prestige goods production and exchange, differential household wealth, and indicators of large-scale militarism), and a significant amount of archaeological research has been carried out on the origins, evolution, and organization of chiefdoms in premodern societies of the Near East, Africa, East Asia, Europe, Mesoamerica, South America, North America, and Oceania. However, there is considerable recent debate about the utility of 'chiefdoms' as a cross-culturally applicable evolutionary concept, with challenges to this archetype ranging from decoupling elements of 'chiefdom' structure, examining these societies at more diverse scales of analysis, and rejecting the 'chiefdom' model in favor of a variety of postprocessual approaches in archaeology. This article reviews this controversy and synthesizes current archaeological approaches to sociopolitical structure, political economy, ideology, warfare, and evolutionary transformations in chiefdoms.

The use of the term 'chiefdom' to refer to prestate complex societies is a relatively recent phenomenon, beginning with Oberg's (1953) historical classification of South and Central American societies and Sahlins' (1963) ethnographic work on Polynesian societies in the 1950s. Service (1962) included 'chiefdoms' a decade later in his neo-evolutionary categories of *band*, *tribe*, *chiefdom*, and *state*, and the concept become closely associated with the cultural evolutionary paradigm developed earlier in the century by such anthropologists as Julian Steward and Leslie White. Almost immediately, archaeologists began to apply the chiefdom concept to investigations of early societies such as the Late Neolithic European builders of Stonehenge and the Mississippian towns of the Southeastern US, which manifested some complexity but generally lacked the long-held archaeological indicators of 'civilization' (e.g., large urban centers, massive kingly tombs, written dynastic histories and legal codes, markets and monetary systems) (Flannery, 1972; Peebles and Kus, 1977; Renfrew, 1973; Wright, 1984). Chiefdoms are included in what archaeologists have increasingly referred to as 'middle range' societies, encompassing the traditional cultural evolutionary categories of both *tribes* and *chiefdoms* and emphasizing the great diversity of social and political structures in societies of intermediate scale and structural complexity between *bands* and *states* (Beck, 2003; Earle, 1991).

Chiefdoms and Cultural Evolutionary Theory

Chiefdoms have been defined by some archaeologists in primarily political terms, as smaller-scale complex societies with centralized decision-making hierarchies of one or two levels above the individual village (compared to three plus levels in states) (Sahlins, 1963; Wright, 1984). Chiefly leaders obtain their political authority through both ascription and performance (compared to largely hereditary kings), they have very generalized administrative roles (judicial, economic, ritual, military), they have few bureaucratic specialists (unlike the specialized bureaucracies of states), and they generally rely on kin-based alliances to structure political relations with subordinates (rather than the nonkin-based political institutions and formal legal codes of states) (Earle, 1991). Most archaeologists would expand the definition to include social ranking that has at least some hereditary component (unlike the achieved ranking of tribal societies and the almost wholly hereditary social classes of early states) and some degree of economic centralization (control over staple production, building and managing irrigation systems, tribute mobilization, control over the production and exchange of prestige goods, and/or foreign trade monopolies) (Brumfiel and Earle, 1987; Renfrew and Shennan, 1982). Chiefs generally maintain their political power not only through varying strategies for accumulating and disbursing material resources, but also through ideological means (manipulating cosmologies, ritual, and myth, and creating power-imbuing sacred landscapes) and military coercion (using strategies of threatened or actual force supported through controlled warrior cadres and military technologies) (Earle, 1997). Chiefdoms rarely exist or evolve in isolation, but instead are found as clusters of interacting *peer polities* that often share aspects of elite culture, have similar structures, and compete for regional supremacy (Renfrew and Cherry, 1986). Many chiefdoms are also part of larger *world systems* that link them to more developed states and empires (Peregrine, 1992)

Chiefdom-level societies have been identified by cultural anthropologists, archaeologists, and historians in many parts of the world and in many time periods (**Figure 1**), often as precursors to state development but sometimes as long-term, stable structures that do not transform into more complex states (*see* States and Civilizations, Archaeology of).

Figure 1 The chronological and geographic distribution of some archaeologically known chiefdoms with varying archaeological indicators. The 'debated chiefdoms' have been variously described as 'tribal' or 'ranked' societies, 'chiefdoms' or 'early states.' Evolutionary transitions marked with '?' indicate cases of disputed cultural/population continuity.

The Polynesian chiefdoms (*see* Pacific Islands, Archaeology of), the pre-Roman (Late Neolithic, Bronze Age, and Iron Age) societies of Europe (*see* Europe, Archaeology of), and eastern North American complex societies (*see* North America, Archaeology of) received the most intense archaeological study in the mid part of the twentieth century. However, archaeologists have more recently expanded their use of the chiefdom model to societies in the Near East, Africa, East Asia, South Asia, Mesoamerica, South America, and western North America (e.g., Feinman et al., 2000; Junker, 1999; McIntosh, 1999; Redmond, 1998; Rothman and Stein, 1994), although the 'evolutionary status' of many as chiefdoms is controversial (e.g., the Woodland Period societies of the Eastern US, the Late Neolithic societies of Europe, the Halaf and Samarran societies of the Near East, and many prestate African societies). Early in the development of the chiefdom concept, archaeologists identified a number of common material correlates of these types of societies (e.g., two to three level settlement hierarchies, monumental architecture, burials with hereditary status indicators, specialist-manufactured prestige goods, regional and interhousehold differences in wealth; see **Figure 1**). However, as more of these complex societies are intensively studied by archaeologists, it has become clear that material patterns, and presumably the ideological, political, social, and economic structures underlying them, vary substantially (Earle, 1997; Drennan and Peterson, 2006; McIntosh, 1999).

Critiques and Refinements of the Chiefdom Concept

A number of recent critiques of the chiefdom concept, and cultural evolutionary models in general, have emphasized the organizational diversity and historical uniqueness that are ignored when anthropologists attempt to fit societies in broadly defined classifications and assume uniform trajectories of development. As noted above, many scholars have pointed out the great deal of variability in societies designated as 'chiefdoms.' One response to this recognized diversity has been to subdivide prestate complex societies into developmentally distinct types, such as Carneiro's (1981) 'minimal,' 'typical,' and 'maximal' chiefdoms (based on complexity of political hierarchies), Johnson and Earle's (1987) 'simple' and 'complex' chiefdoms (based on scales of chiefly political, economic, and ritual control), and Renfrew's (1973) 'group-oriented' and 'individualizing' chiefdoms (based on differing strategies of lineage vs individual aggrandizement and social display).

Some scholars have emphasized that transformations in social, political, economic, and ideological structures that have previously defined chiefdoms do not always occur in tandem and should be studied independently as trajectories of change (Earle, 1997; Feinman and Neitzal, 1984). Other archaeologists have criticized the simplistic emphasis on hierarchical socio-political structures in chiefdoms (McIntosh, 1999), emphasizing *heterarchy* (Ehrenreich et al., 1995), or nonhierarchical or horizontally binding relations that operate along multiple dimensions (social, economic, political, ritual) to structure these societies.

While many archaeologists favor continual refinement of the chiefdom concept and its continued utility in comparative archaeological research, others have largely advocated its abandonment, citing the misplaced archaeological search for the roots of 'chiefdom' emergence and structure in systemic evolutionary processes, elite-centered viewpoints, and largely economic-focused notions of power (Pauketat, 2007; Yoffee, 1993). New approaches in the last several decades to the archaeological study of emerging complex societies include 'actor-based' methods of analysis focused on the agency of individuals and groups in shaping power relations, Marxist theories of political control that emphasize the ideological and symbolic bases for structure, and 'interpretive' approaches that recognize Western and capitalist bias in modeling ancient societies (Dobres and Robb, 2000; Hodder, 2012). Shared among these postprocessual critiques is the recognition that both structure and change in complex societies are contingent on highly variable social and environmental landscapes, as well as unique historical circumstances. In addition, there is an increasing emphasis on studying these societies at multiple scales, ranging from individual actors and interest groups within the society to expansive networks of interacting polities, using new spatial and quantitative tools such as *social network analysis*. Despite these criticisms, revisions, and outright rejections of the chiefdom concept, the term 'chiefdom' as a designate for these societies and key elements of political, social, economic, ideological, and military structure defining it, remain highly visible in archaeological work, cross-cultural comparisons, and theoretical dialogue. Therefore, subsequent sections examining these prominent aspects of chiefdom organization focus on the work of scholars who continue to find this a useful analytic concept.

Political and Social Features

Chiefdoms are characterized by partially inherited and partially achieved political leadership, reinforced through ideological manipulation, control of economic resources, and militarism (Earle, 1991). The political power of chiefs is often reflected materially in symbols of office, such as the feather capes of Polynesian chiefs (Kirch, 1984) and the stone maceheads of Gerzean Period predynastic polities in Egypt (Bard, 1994), and in monumental architecture which demonstrates a chief's ability to control and mobilize large labor forces (e.g., the henge monuments of Late Neolithic Europe and the monumental statuary of Formative Period Mesoamerica and Easter Islanders (Kolb, 1994; Renfrew, 1973)). Chiefly centers, as the focal point of political, economic, and religious activities of chiefs, are generally archaeologically distinguishable from subordinate villages by their greater size, centrality, and presence of monumental architecture, wealth objects, and specialized production locales. Multiple levels of political authority (*paramount chiefs* and local chiefs) typical of larger-scale chiefdoms are often archaeologically visible in regional settlement hierarchies of up to three levels (Cobb, 2003; Drennan and Peterson, 2006; Peebles and Kus, 1977; Wright, 1984).

A number of archaeologists have offered new conceptual frameworks for analyzing differing political power strategies in chiefdoms. One model offered by Blanton et al. (1996), contrasts *network* vs *corporate* strategies of political dominance, elaborating Renfrew's earlier distinction between individualizing and group-oriented chiefdoms. These differing strategies are viewed as part of political dynamics in all complex societies, but political actors in a particular society may emphasize one mode of control more than the other. In a network strategy, political actors try to create personal networks of dominance through the strategic distribution of portable wealth and symbolic capital (e.g., ritual potency and religious knowledge). The emphasis on individual aggrandizement is archaeologically manifested in lavish individual burials, elaborate household wealth display, and competitive presentational events such as ceremonial feasting. The highly conflictive nature of leadership and long-term instability of political configurations are evidenced in rapidly changing settlement hierarchies. In contrast, a society emphasizing a corporate political strategy disperses power across different groups and sectors of society through bureaucratic institutions promoting consensus, solidarity, and collective action, often reinforced through archaeologically visible public architecture, collective tombs, and unifying emblems (e.g., the henge monuments, copper axes, and collective mound tombs of Late Neolithic chiefdoms of Europe; the massive earthen burial mounds topped by wooden buildings and shell and copper valuables of Mississippian chiefdoms of North America) (Renfrew, 1973; Peebles and Kus, 1977). Beck's (2003) work on Mississippian chiefdoms in the American Southeast has framed these varying strategies similarly, but around issues of relative scale and mobility of economic resources and labor, with *coercive expansion* and *persuasive aggregation* working alternatively or even simultaneously to form *apical* (i.e., top-down) and *constituent* (bottom-up) forms of political authority.

In terms of social structure, chiefdoms invariably have some form of ascribed social ranking (Sahlins, 1963). While social status differences are characteristic of all human societies, social ranks in chiefdoms are at least partially inherited intergenerationally, they are given structural rigidity through behavioral taboos and symbolic expression, and in most cases, there is distinct economic advantage (differential access to resources) conferred on an elite stratum. Social stratification in chiefdoms is often manifested in archaeologically visible rank insignia (e.g., the shell gorgets of Mississippian chiefs in the American Southeast and the jade ornaments of China's Longshan chiefdoms) (Barnes, 1999; Cobb, 2003), differential wealth in households (e.g., imported Chinese porcelain fragments in fourteenth to sixteenth centuries Philippine chiefs' pile-house remains) (Junker, 1999); and varying size and complexity of residential architecture at

settlements (e.g., village house-clusters in Hawaiian chiefdoms; Kirch and Jones, 2003).

Ascribed rather than strictly achieved social ranking is most archaeologically evident in burial practices. Inherited status is generally expressed through variation in body positioning, body treatment, grave forms, and burial accompaniments, which cross cuts age and sex categories, making it archaeologically distinguishable from mortuary variability attributable to age differences, gender roles, and achieved statuses. Mortuary analyses based on this premise have been carried out most successfully at Mississippian, Chinese Longshan, Egyptian Gerzean, and Bronze Age and Iron Age European cemeteries (Bard, 1994; Barnes, 1999; Cobb, 2003; Gilman, 1981), where relatively large samples of well-preserved burials have allowed the identification of distinct social hierarchies. In cases where larger burial populations are lacking, archaeologists have frequently made an argument for the presence of elites based on finds of elaborate, often monumental chiefly burials (e.g., jade-yielding Formative Period Mesoamerican tombs, the Nok and other mounded tombs of West Africa, the Yayoi stone-lined crypts of Japan) (Barnes, 1999; McIntosh, 1999). Status-related dietary and health differences between elites and non-elites have also been studied through zooarchaeological and paleobotanical analyses of food remains at settlements, and through osteological assessments of nutritional stress and disease in burial populations (e.g., Blanton et al., 1996; Kirch and Jones, 2003).

Political Economy

Just as chiefdoms studied by archaeologists vary in political structure, they differ in the ways in which chiefs attempt to assert economic control in support of their governing institutions. Brumfiel and Earle (1987; Earle, 1997) have made a useful distinction between strategies of *staple finance* and *wealth finance* in chiefdoms. Staple finance involves the systematic levying of tribute payments (in the form of staple goods and/or labor) from subjugated commoners, with the revenue used to directly finance activities such as monument-building, warfare, trade, and ceremonial feasting that enhance the authority of the chief. Since control of land and its production is essential to staple finance, chiefdoms emphasizing this economic strategy generally have strongly developed institutions for land tenure (archaeologically manifested in boundary features such as walls and corporate monumental structures) and significant chiefly investment in agricultural intensification (archaeologically manifested in large-scale irrigation works, water control, and artificial terracing) (Kirch, 1984). Archaeological investigations suggest that the Hawaiian chiefdoms, pre-Inca South American chiefdoms, and many prestate Mesopotamian complex societies had political economies dominated by staple finance (Blanton et al., 1996; Brumfiel and Earle, 1987; Earle, 1997; Rothman and Stein, 1994).

Wealth finance involves the use of prestige goods or valuables as political currencies by chiefs and other elites, to cement alliances with other elites and to reward subordinates for loyalty and service (particularly associated with a network political strategy). Prestige goods vary according to socially defined standards of value and can be any rare or easily controlled objects, such as: jades in Longshan China (Barnes, 1999), gold in Central American chiefdoms (Helms, 1993), bronze in European chiefdoms (Earle, 1997), and shell and copper ornaments in eastern North American chiefdoms (Cobb, 2003). Politically charged wealth can be locally manufactured or obtained through foreign trade. Emerging elites control access to this political currency through support of *attached specialists*, highly skilled artisans who produce these goods wholly for elite consumption; by monopolizing valuable raw materials and technologies; by dominating trade routes; and by defining limited social contexts for their circulation, such as elite-controlled ceremonial feasting events (Brumfiel and Earle, 1987; Schortman and Urban, 2004). While specific chiefdoms tend to emphasize one means of economic control over another, chiefs tend to use elements of both staple finance and wealth finance in varying combinations, resulting in unique forms of political economy (Earle, 1997).

In addition to the emergence of attached specialists, the rise of chiefdoms is sometimes accompanied by the growth of *independent specialists*. Independent specialists are full-time craft production specialists who concentrate at chiefly centers due to economies of scale and produce more mundane household goods for an unrestricted set of consumers. While the archaeological recovery of large-scale craft workshops containing mass-production equipment (e.g., large kilns or smelting furnaces, molds, potter's wheels) is the most direct line of evidence for specialist production, such finds are rare. More often archaeologists have assessed craft production modes through analysis of the products themselves and their regional distribution. Specialized production by a limited number of concentrated, recurrently interacting, full-time craftsperson (either attached specialists or independent specialists) generally results in a more standardized product, as measured through object form, raw material, and/or decoration. In addition, specialist-produced prestige goods are largely restricted to elite centers, while household-produced domestic goods are widely dispersed throughout a region, and the socially unrestricted products of independent specialists are concentrated at, but not restricted to, regional centers (Brumfiel and Earle, 1987; Earle, 1997; Schortman and Urban, 2004).

Particularly in chiefdoms relying heavily on wealth finance, political relationships, and hierarchies of authority are reinforced through the continual circulation of prestige goods, most often in the context of bridewealth exchanges (e.g., gifts of porcelain in Southeast Asia and gold in Panama; Junker, 1999), political investitures (e.g., the presentation of feather capes in Polynesia; Earle, 1997), ritualized feasting, and other politically charged events. Of these exchange contexts, ritual feasting is particularly evident in the archaeological record. Archaeologists have identified feasts that were likely aimed at political integration and competitive status display using evidence, including: specialized feasting paraphernalia like bronze drinking vessels in the European Iron Age or large ceramic cooking vessels in Mississippian and Formative Mesoamerican chiefdoms; unusual food remains such as large pig concentrations in Longshan China; and the association of similar artifacts and ecofacts with ritual architecture like Mesoamerican ballcourts (Dietler and Hayden, 2001; Kirch and Jones, 2003).

The Ideology of Rulership

Ideologies are collective representations of the social and political order in particular societies, often encoded in myths, ceremonies, and various public performances, but also frequently materialized in archaeologically visible monumental architecture, iconography, and portable objects. In both state-level societies and chiefdoms, the creation of a dominant ideology and its imposition on the populace are an important basis for power (Earle, 1991; Pauketat, 2001). In many chiefdoms, elites developed their own language, dialect, lexicon, and/or notational systems to control the flow of esoteric knowledge and to restrict the performance of religious rites. The archaeological contexts in which written texts are found and their decipherable content (e.g., inscriptions found with monumental earthen works in Formative Period Mesoamerican centers, imported Sanskrit-based writing or Arabic scripts on bamboo in historic chiefdoms of island Southeast Asia) (Blanton et al., 1996; Junker, 1999) suggest that literacy was an elite prerogative which served to institutionalize cosmological notions and to legitimate the political and social domination of elites.

In the absence of written texts, archaeologists often infer shared cosmic orders and ruling ideologies from iconography on portable objects like were-jaguar figurines of Formative Period Mesoamerica, 'sun' motifs and other symbols on Mississippian pottery (Cobb, 2003), 'patron-deity' symbols on Egyptian Gerzean stone palettes and maces; from monumental constructions (e.g., the platform temple complexes of Polynesia, the henge monuments of Late Neolithic Europe (Earle, 1997)); from material symbols in burials (e.g., painted scenes in Japanese Yayoi mounded tombs (Barnes, 1999)); and from the spatial organization of chiefly centers (e.g., the layout of Cahokia and other Mississippian centers (Cobb, 2003; Pauketat, 2001)). An influx of exotic symbols representing foreign cosmologies or religious beliefs (e.g., Buddhist and Hindu art and architecture in Southeast Asia, widespread Olmec styles in Formative Period Mesoamerica, Egyptian themes in the early Nubian chiefly tombs of Kerma) has often been interpreted by archaeologists as a particularly effective strategy for chiefs to add to their monopolistic store of power-enhancing knowledge.

While past archaeological research has largely focused on ideologies of domination in chiefdoms, many researchers now recognize that the many individuals and social factions comprising these complex societies have distinct, and sometimes conflicting, world views based on personal experiences and interests. Increasingly, archaeologists are attempting to tease out diverse values and perspectives related to gender, class, ethnicity, occupation, and individuality (Dobres and Robb, 2000).

Warfare and Militarism

Anthropological studies have suggested that warfare in chiefdom-level societies differs from that in tribal societies by its expansionistic focus on acquisition of territory, resources, and captives and by its concentration of military power in the hands of chiefly leaders who use it to expand their political sway. In an early study of chiefdoms, Carneiro (1981) suggested that both the rise and expansion of chiefdoms were related to warfare. Under conditions of land shortages and population stress, militarily powerful leaders systematically assault settlements along polity boundaries and conquered enemies were incorporated into the expanding chiefdom, resulting in the coalescence of a polity of greater complexity as well as scale. However, ethno-historic work on chiefdoms with 'low-density' populations and abundant resources and land (e.g., in island Southeast Asia, the Caribbean, and parts of Africa), shows that large-scale and highly organized warfare and seemingly perpetual raiding is endemic but not generally related to resource stress and territorial conquest aims (Junker, 1999). In fact, in early historic island Southeast Asian chiefdoms, slave-raiding was the most prominent form of militarism, a practice that can be connected to labor shortages rather than population pressure on resources. Warfare seems to be an almost continuous occurrence in many chiefdoms, one of a number of forms of peer polity interaction that are politically transformative in a variety of ways. Political loyalties may be shifted to military victors who control the ideology of warrior prestige and who increase their political currency through captured labor and valuables, resulting in larger alliance networks (Earle, 1997; Kirch, 1984; Kolb and Dixon, 2002).

Archaeologists have focused on a variety of material evidence to document changes in the scale, intensity, and behavioral and ideological aspects of warfare in chiefdom-level societies (*see* Conflict and War, Archaeology of: Behavior and Social Organization). These include the development of fortifications or other defensive works, changes in regional settlement patterns (e.g., concentration of population in large centers, depopulation along polity boundaries, relocation of settlements to defensible positions), systematic destruction of power-symboling architecture (e.g., dismantling of monumental architecture, toppling of statuary, burning of chiefly centers)(Cobb, 2003; Kirch, 1984). Examples are the alternating rebuilding and burning of fortifications surrounding Iron Age European towns such as Heuneberg and the creation of 'no man's lands' between Mississippian centers (Cobb, 2003), and the defacement of sacred monumental statuary on Easter Island (Kirch, 1984). Osteological evidence from burials allows archaeologists to evaluate rates of violence in populations (e.g., scalping, skeletal trauma, embedded projectiles), the ritualized use of body parts in prewar and postwar ceremonialism (e.g., decapitation for trophy head-taking), and debilitating physical conditions and malnutrition related to prolonged exposure to military siege (Kolb and Dixon, 2002). Archaeological studies of burials also allow archaeologists to identify 'warrior insignia' associated with the development of specialized warrior classes and strong ideologies of warrior prestige, exemplified in the elaborate bronze horse fittings of Bronze Age European warriors and the gold-pegged teeth of island Southeast Asians warriors (Carman and Harding, 1999; Junker, 1999). The development of new warfare technologies associated with escalating military competition can be traced archaeologically in intensified metals mining, 'hoards' of weaponry stored for battle (e.g., sling stones at Polynesian sites), labor-saving equipment (e.g., molds for mass-

producing bronze weapons and arrowheads in Bronze Age Europe and Metal Age Southeast Asia) or large-scale facilities for mass-production of weapons (e.g., the sometimes massive iron smelting areas in Iron Age European fortresses), and the adoption of horses for mounted cavalry (e.g., the horse-riding warrior images in Japanese Yayoi and Kofun tombs) (Barnes, 1999; Carman and Harding, 1999; Earle, 1997; Junker, 1999; Kolb and Dixon, 2002).

The Evolution of Chiefdoms

Many archaeologists view the transition to inherited, institutionalized power and status, associated with chiefdoms but further developed in states, as the key transformation in human societies. Since the organizational dynamics of chiefdoms are viewed as similar to that of states, theories of state development are commonly applied at the chiefdom level (Flannery, 1972; Wright, 1984). Early theories emphasized the managerial benefits of chieftainship as societies expanded in scale. Chiefs arose to administer irrigation works (Wittfogel, 1957), coordinate localized production and exchange (Service, 1962), mediate land conflicts and warfare (Carneiro, 1981), ameliorate economic risk through ritual intervention (Drennan, 1976), and to meet other organizational challenges.

More recently, archaeologists have criticized the functionalist nature of these theories and their simplistic emphasis on single factors, instead focusing on the varied acquisitive and power-seeking strategies of political actors as they vie for symbolic capital and control over the labor and resources of others (Earle, 1997). In this view, the origins of permanent forms of social inequality and political authority are to be found in the competitive and aggrandizing behavior of 'big men' in tribal societies. Archaeologists now examine this transformation at varying scales of analysis, ranging from the transfiguring actions and motivations of individual political actors (Dobres and Robb, 2000), to multiple polities developing in tandem through forms of peer polity interaction (Renfrew and Cherry, 1986), to change-stimulating contacts with more complex states and empires (world systems theory).

In addition, many archaeologists now recognize that not all chiefdom-level societies have unilinear evolutionary trajectories leading inevitably toward greater complexity. Many chiefdoms fail to develop state-level institutions over the long-term, instead perpetually cycling between complex and simple forms, 'devolving' into tribal societies (e.g., New Zealand's South Island Maori, possibly Amazonian societies), mysteriously collapsing (e.g., Mississippian chiefdoms, Easter Island), or otherwise maintaining a chiefdom-level organization until eventual absorption by colonizing states and empires (e.g., many chiefdoms of the Central American Isthmus, North America, the Caribbean, island Southeast Asia, Europe and Polynesia). As noted in the critiques of cultural evolutionary theory, other scholars reject the notion of 'chiefdoms' as a structural type in human societies altogether (as argued forcefully by Yoffee, 1993) and the explanation for their rise and fall is as varied as the 'chiefdoms' themselves.

This article is a revision of the previous edition article by M.H. Schmidt, A. Maras, volume 3, pp. 1676–1682, © 2001, Elsevier Ltd.

Abstract

This article begins with a brief review of child and adolescent psychiatry (CAP) as a distinct medical discipline and also the training required to practice it. We also briefly consider the options when there is a shortage of or no child psychiatrists available to deliver care. There is a short discussion on the features that distinguish CAP from other specialties. The influence of culture, development, family, and school are discussed. This is followed by outlining the principles of an effective approach to delivering high-quality care for children and young people. This article will not consider the presentation or treatment of specific disorders.

Introduction

This article begins with a brief review of child and adolescent psychiatry (CAP) as a distinct medical discipline and also the training required to practice it. There is a short discussion on the features that distinguish CAP from other specialties. The influence of culture, development, family, and school are discussed. This is followed by outlining the principles of an effective approach to delivering high-quality care for children and young people. This article will not consider the presentation or treatment of specific disorders.

Terminology

For the ease of the reader, the word child is used to denote all those under the age of 18 years. The word adolescent is used specifically to refer to those aged 12 and above.

CAP as a Distinct Medical Specialty

CAP is a relatively young specialty and in many ways continues to be a developing one especially in middle- and low-income countries. In some countries, CAP has well-established roots as a separate specialty, whereas in others, the work is carried out by general psychiatrists or pediatricians. Training in CAP varies widely across international contexts and there is a large disparity of standards and practice in CAP including European countries where it has been formally compared (Simmons et al., 2012). This may be due to the wide variation in historical origins of the specialty. In the United States, CAP has its origins in the post second war guidance clinics. In the United Kingdom, it was promoted through some of the work undertaken by psychotherapists and further cemented by epidemiological studies indicating the level of unmet need. The changing views of children and the notion that children had specific rights may also have played a part (O'Reilly et al., 2013).

Of the 34 European countries for whom data was collected about child psychiatry (Simmons et al., 2012), six (Belarus, Bosnia, Ukraine, Malta, Russia, and Spain) reported that there is no official CAP training program. The remaining 28 participants, who were Austria, Belgium, Croatia, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Israel, Italy, Latvia, Lithuania, The Netherlands, Norway, Poland, Portugal, Romania, Serbia, Slovakia, Slovenia, Sweden, Switzerland, Turkey, and the United Kingdom, reported official CAP training programs. In 7/28 countries (25%), there is a core common trunk in general psychiatry before trainees specialize in CAP; 19 countries (68%) do CAP from the start of psychiatry training, and 2 countries (7%) start CAP training straight from medical school. All the respondent countries, except Greece, have national training standards for CAP, although only 11 reported their rigorous implementation. Countries use a number of assessment strategies ranging from oral and written exams to submission of a curriculum vitae, research thesis, or analysis of video recordings. Canada, Australia, New Zealand, and the United States all have recognized pathways for specializing in psychiatry. In common with some European countries including the United Kingdom, these countries all require some general medical training after qualification from medical school and some training in general psychiatry. Training varied in terms of time from very little time up to 5 years and more. Other countries that also have formal CAP programs include Morocco (since 2007) and Paraguay has started such training in 2013. Recruitment into CAP is a problem in a significant number of countries, and appropriate training opportunities are issues for developing countries (e.g., Pakistan; personal communication).

There are difficulties in ensuring that there are enough appropriately trained clinical staff to meet the mental health needs of children given the increasing prevalence rates.

In situations where there is no direct access to a child psychiatrist or a severe shortage, provision of services requires other staff such as general practitioners, pediatricians, or adult psychiatrists to develop special interests to ensure the mental health needs of children are met. Another option may be to train up nursing staff or other staff (for example, teachers) who have access to families for other reasons such as delivering maternity or educational services, respectively. Training should allow staff to deliver care for the problems most encountered in their context. This requires applying the principles described

below. Clearly, it is important for staff to be supported and this may be done through links with centers that have child psychiatrists who are able and willing to provide consultation and support. There are examples of modern technology being used to provide support to those delivering frontline services and the potential of this in child mental health has yet to be fully realized. There are also a number of training opportunities specifically aimed at non-mental health specialists to develop their understanding of child mental health. Eapen et al. (2012) wrote to specifically address this issue by suggesting that staff working in primary contexts such as primary health care or education could make some basic provisions. It is probably best to be open with families about the potential limitations so that they are fully aware of what may or may not be available. In these situations CAP may have a greater role in consultation and supporting staff rather than providing direct care.

The models to deliver services will need to take local contexts into account. The World Health Organisation states that "Mental health promotion requires multi-sectoral action, involving a number of government sectors and non-governmental or community-based organizations. The focus should be on promoting mental health throughout the lifespan to ensure a healthy start in life for children and to prevent mental disorders in adulthood and old age."

The challenge may be in thinking about how we can promote children's mental health with whatever limited resources are available. The reality is that if we continue to wait for the perfect time and adequate resources, nothing may materialize.

What Distinguishes Child Psychiatry?

The key features that distinguish the practice of CAP from general adult psychiatry are the following:

- Nowhere is development more marked than in childhood and adolescence.
- Children have to be viewed in the context of their families on whom they are generally dependent and definitions and compositions of the families are changing all the time.
- The cultural context of the child is even more significant as both the first two features are related to this aspect.
- Most often, nominated patients do not present themselves but are presented.
- Cultural mismatches between young people and their carers that may affect presentations to mental health services and how they are managed.

Social Contexts and Experiences

Social factors are, to varying degrees, of undoubted importance in the prevention, development, and maintenance of mental health problems including those of childhood. As Jenkins (2008) highlights, disentangling genetic from environmental influences is not easy.

Bronfenbrenner's (1979) model of layered contexts is a fairly widely used model to try and understand the various factors that need to be considered when thinking about CAP. The layers are the microsystem, mesosystem, exosystem, and macrosystem. The first layer (microsystem) is at the level of the relationships in which the child is actively involved, for example, with parents, siblings, and peers. These interactions inevitably depend on context and the child's characteristics (or personality). The mesosystem describes how the different components of the microsystem come together. The exosystem is the wider local community such as the neighborhood. The macrosystem is usually more remote, but may still be a major social influence, for example, through socioeconomic policy on child rearing, education and health policies, and wider social and cultural contexts. It is worth noting that different factors may be important at various stages of the child's life. Some adverse family factors may be mitigated by external factors that come into play as children get older (e.g., peer support). Those working in CAP need to be aware of the dynamics and the interplay between the different layers.

Cultural Considerations

Culture itself influences the way that children and their perspectives are viewed (Dogra, 2010; Dogra et al., 2007). Although most countries have signed up to international agreements, there is still huge variation in the value that children are accorded (O'Reilly et al., 2013). Among many issues, culture in its broadest sense (see Dogra, 2010) influences

- the meaning of childhood and expectations of children
- the way developmental milestones and family development are viewed
- parenting styles
- the interpretation and meanings of the symptoms that may be present
- religion
- views of gender.

An understanding of the cultural context may help clinicians make sense of the presentations and formulate the issues in ways that are acceptable to the family and thereby amenable to intervention. There are very few culturally specific problems. However, some disorders are more likely to occur in some contexts than others (Dogra et al., 2007). For example, the eating disorder anorexia nervosa is more common in Western contexts than others. Rousseau et al. (2009) surveyed the literature on culture and Diagnostic and Statistical Manual of Mental Disorders (DSM)-IV in child psychiatry. They concluded that, although the DSM-IV diagnostic categories may be found cross culturally, clinicians need to be aware of how culture may influence the diagnostic process.

Family Environments

One cannot think about child psychiatry without considering the family and the part it plays in the child's life. While the precise makeup of families may be culturally variable, the concept of the family is universal.

Parenting

The role of parenting is to adequately nurture the child and prepare them for adulthood (whether that is independent living or living in an adult role within an extended family). Parenting styles are strongly influenced by broader cultural and political factors. There are widely accepted to be four different types of parenting styles that bring with them different advantages and disadvantages. Baumrind (1966) identified authoritative, authoritarian, and permissive parenting styles. Macoby and Martin (1983) divided permissive parenting into two subtypes – neglectful and indulgent. Awareness of parenting styles and how these impact on the child are of relevance in child psychiatry.

Authoritative Parenting

Authoritative parents make demands that fit with their children's ability to take responsibility for their own behavior. Children, it is suggested, subsequently learn that they are competent individuals who can do things successfully for themselves, which then fosters high self-esteem, cognitive development, and emotional maturity. Characteristics of authoritative parenting include emotional support, clear bi-directional communication, firm limit setting, reasoning, and responsiveness (Baumrind, 1966). Warm supportive parenting aids child development and helps children to regulate their own emotions and behaviors. It may also be protective in adverse circumstances. Children are more likely, according to this framework, to learn to express their perspective in a constructive socially accepted way. This is because there is appropriate modeling and the parents are responsive to their child's needs. This type of parenting requires a secure attachment with the primary caregiver, a positive relationship between the parent and child, and age-appropriate and consistent disciplinary practices, e.g., reasoning with a younger child may be inappropriate in the context of the child's development.

Authoritarian Parenting

In contrast, authoritarian parenting is described as punitive and directive. Again stereotypically, parents who use this style are unlikely to discuss rules and will emphasize discipline and obedience (Baumrind, 1966). The views of young people are deemed to be of little importance irrespective of age. It is implied that this style is not responsive to young people's emotional needs; however, in practice, this may not be the case.

Permissive Parenting

Both permissive styles of parenting – neglectful and indulgent – make few demands on children, with limited boundaries. In the case of neglectful parenting, there is reduced care or supervision (Macoby and Martin, 1983) and, in extreme form, there is a lack of responsiveness to the needs of children, emotional or otherwise. Indulgent styles may also be problematic as again there are limited boundaries – the child is just given everything (Baumrind, 1966). There is evidence that 'overindulged' children show poor emotion regulation (underregulated) and rebel when they cannot have their own way. 'Overindulgent' parenting may be used to avoid having to deal with the conflicts that may arise or to manage parental separation and hostility.

Development

There is no doubt that culture influences child rearing and the way children are encouraged to grow up. Culture influences the nature of their relationships with peers and siblings and the roles and responsibilities that accompany their development. The key areas of development are physical, emotional, social, cognitive, and moral development. Culture can influence all aspects of development but it can be difficult to identify exactly how it influences any particular child as there will be other complex dynamic features at work. The influences on social and emotional development are most evident.

As already discussed above, parenting styles may be influenced by cultures. However, families are in many ways unique entities of their own. It is often difficult to define what a family is because the 'nuclear' family that so many of our ideas are based on is increasingly changing in shape and content. CAP is frequently influenced by the notion of the family life cycle outlined by Carter and McGoldrick (1989). Despite its limitations, the Carter–McGoldrick model highlights that life and development inherently bring with them changes in social context and practice. The way that families as a whole or individuals within that unit manage that change has implications for all members of the family. While the stages of the family life cycle may be variable between and within cultures, the concept of different stages of development is likely to hold true. Practitioners can compare their own experiences and those of the families they have worked with using the model as a benchmark. It becomes unnecessary to debate whether the model is right or wrong but it offers families and staff stages that can be considered whatever the context.

School Environments

After home, school is where children spend most of their time, so it is unsurprising that school environments and experiences are an important factor when considering the mental health of children. Schools can have a very positive impact on children and mitigate some of the negative impacts of other social factors, including aversive home environments (Mortimore, 1995). However, for some young people they can be a considerable source of stress, worry, and unhappiness, particularly if bullying is experienced. Elias et al. (1997) argued that schools are most successful in their educational mission when they promote academic, social, and emotional learning. This approach recognizes that emotions can facilitate or hamper young people's learning, which in turn influences their mental health.

There are many factors such as poverty, war, and trauma that are beyond the scope of interventions that can be applied by CAP on a case by case basis. However, the

influences of these on the child's mental state need to be borne in mind especially by those who work with children with mental health problems but are not specifically trained in the area.

Whose Perspective Is Most Valued?

In child psychiatry, there is the additional complication that the clinician has to deal with different viewpoints within the family, which will impact on the assessment and treatment that can be agreed. Cultural and family factors clearly influence whose perspective in the family is afforded the greatest value but the clinician working within CAP has to balance all perspectives. Garland et al. (2004) interviewed 170 adolescents, their caregivers, and their therapists to identify three desired outcomes for each stakeholder. Almost two-thirds of the triads did not agree on even one of the desired outcomes for the adolescent's treatment when desired outcomes for individual cases were compared. Essentially, there was a lack of agreement of the desired outcome among key stakeholders or desired outcome priorities for adolescent services. Williams et al. (2011) found low parent–adolescent concordance on perceived need for help, with a greater proportion of adolescents reporting a need compared to their parents. Concordant dyads kept a higher number of appointments than discordant dyads. A study by Roberts et al. (2005) comparing concordance between parent and child in different ethnic groups found that ethnicity is a significant factor in parental labeling and awareness of adolescent mental health problems. This lack of consensus may limit engagement in treatment and the effectiveness of care and this highlights a fundamental issue for child and adolescent mental health service (CAMHS) in identifying who the client is and whose needs are prioritized. Parents may attend and/or support their child's attendance depending more on how they feel than whether the child requires help or not.

It is clear that these factors strongly influence emotional and social development and a sense of self. How the child's sense of self, parental, and wider expectations interplay in the cultural context with each other are of great relevance in the practice of child psychiatry.

Principles of an Effective Approach To Service Delivery

Context of Child Psychiatry Services

Most child psychiatry care is delivered in the outpatient community setting, with some being delivered in day centers and some in inpatient units. Generally, inpatient care is reserved for those at high risk or those who are so seriously ill that they need constant nursing and/or medical attention. Outpatient teams are dependent on local resources but multidisciplinary teams are generally viewed as an effective way to deliver services, although the evidence for any approach is relatively limited.

There is also the issue of whether child psychiatry services should be part of mental health provision or pediatric/child services. This is best answered by considering the conceptual, theoretical, and practice issues in turn. While child psychiatrists and paediatricians at first sight may appear to have much in common, there may be little commonality in their approaches. The etiological and treatments of child and adult psychiatry share more in common than pediatrics and child psychiatry. In developing countries, the pressures to deal with physical health problems may mean that the emotional health of children is always relegated to second place if it is even on the agenda. However, there is evidence that children experience mental illness whatever their background and sadly we also know that the stigma surrounding children with mental illness is a universal phenomenon (Leighton and Dogra, 2009).

High-Quality Services

There is increasing debate about what constitutes high-quality child psychiatry care. The Institute of Medicine (2001) quality framework identified that quality care is timely, efficient, effective, patient centered, equitable, and safe.

Assessment in CAP

Most Western contexts would argue for services to be child centered but the meaning of child centered will depend on local contexts. Whatever the approach, good practice in CAP does need the psychiatrist to keep the child's interests as paramount and pay attention to them and their needs whatever other pressures there may be. This section will outline the structure of a CAP assessment before dealing with interviewing children as summarized in **Box 1**.

The structure of the assessment is fairly standard, although surprisingly there is little evidence for why we use this format. Renou et al. (2004) identify that the structured interviews used for CAP research are not practical for clinical practice, although work to improve the reliability of the assessment is ongoing. Hirsch (2013), in describing the practice at a New York facility, states that they send out a packet of questionnaires and rating scales ahead of the first interview. This is probably not appropriate or possible except for some research facilities. Questionnaires cannot replace good clinical practice and interviews remain the best way of undertaking a CAP assessment. There is a need to be flexible about the order and the way in which information is collected. It can be helpful to start by talking about areas

Box 1 Key components of a comprehensive CAMHS assessment

- Presenting concerns and history of these
- Family history
- Social history
- Developmental history
- Risk assessment
- Mental state examination of child
- Observation of young people with their carers
- Formulation and care plan

such as school, family, or hobbies before raising the 'problem' to help the child become comfortable. Good practice means that often children do not even realize they are participating in an assessment as the style is conversational and not interrogative.

Setting the Context

It is important to clarify what the child and/or their carers are expecting and what they know of the service. It is also important to establish their expectations and hopes for the meeting. Consent and confidentiality issues are best addressed early on and it can be helpful for the child to know that there are clear boundaries and that their perspective is as important as those of any adult.

Presenting Concerns

It is important to establish what the child and their family think are the main worries. These may be different from what the referrer has told you, and the relative importance given to different things may vary between different members of the family too. An accurate history of how long the symptoms or worries have been present may also give a clue to precipitating factors and the need to examine how these have affected people differently.

Family History

This involves identifying who is in the family and what constitutes the family from the child's perspective. A genogram (as shown in Figure 1) can be a useful way to demonstrate who is in the family and family relationships. Parental experiences of parenting may be relevant and dependent on the history; this area will be touched upon or explored in more detail.

Social History

This usually means asking the young people about their peer relationships and their interests. As children get older, they begin to have more contacts outside of the family. This is a good opportunity to find out what is of interest to the child and can be a good place to begin interviews as it helps engage with the child. As children become older, asking them about peer activities becomes more important. Young people may be reluctant to share all aspects of this part of the history with their carers. Drug and alcohol history is an important part of the social history, though again sensitivity may be required in getting honest answers from young people about their use of substances and alcohol.

Figure 1 An example of a genogram.

Developmental Assessment

Given that children and young people are developing toward maturation for adulthood, a developmental assessment is a key component of a comprehensive child and adolescent mental health assessment. A developmental assessment is a structured evaluation of the child's development and a comprehensive assessment needs to cover the key domains – physical, social, emotional, moral, and intellectual. Such an assessment is likely to involve several members of the multidisciplinary team (e.g., formal intellectual assessment is best undertaken by a psychologist who has specific training in this; an assessment of motor development, a component of physical development may be best undertaken by an occupational therapist). It will also usually involve seeing the child in different contexts and environments. While this may not be within the exact remit of CAP, the reality is that many referrals to CAMHS have developmental components as potential etiological factors and even if a developmental assessment has been undertaken it may be insufficient.

Why Is Development Important To Consider?

Consider the symptom of 'inattention and poor concentration.' In a 3 year old, this is not unusual, so a diagnosis of attention deficit disorder is unlikely to be appropriate. However, a child who is 7 years of age but with global developmental delay may still have features of inattention and poor concentration. Only a detailed assessment could clarify the situation and an initial assessment establishes whether the child's development is appropriate or not. Unless there is a clear understanding of a child's level of functioning and understanding, it is difficult not only to make an assessment of their presentation but also to identify the appropriate intervention.

Risk Assessment

Risk management is an integral component of a CAP assessment and is especially important with an increasingly litigious society. The nature, source, and assessment of the risks assessed should be clearly recorded. There is the risk children may present to themselves, the risk to others, and also the risk they may be at from others. In CAP, almost all of the children seen in specialist services will be seen with an adult who has parental responsibility for the child and therefore effectively carry some of the responsibility for managing the risk associated with that child. Any risk management plan associated with preventing further occurrences of self-harm, for example, is likely to require their input. There may well be a number of complicating factors within the relationship to take into account, but

the adult carer also has some responsibility to protect and safeguard the child.

Mental State Assessment

In children, this will usually include the form of an observation of behavior, particularly in relation to how they interact with their parents (or carers), siblings (if present), and the clinician. This may take the form of looking for normal developmental markers as well as social skills, appropriate eye contact, and looking for unusual or odd behavior. In older children and young people, this may be a much more formal process, looking at issues more familiar to a mental state examination as in adults. In some older children seen in contexts such as specific 'drop-in' services or those that do not wish for their parents or carers involvement, the interaction between family members may not be possible to observe. Observations need to be done in context of what is appropriate for the child or young person's developmental stage, as outlined above. What is appropriate at a very young age may be interpreted as 'clinginess' for a slightly older child. Attachments to family and carers become looser in adolescents where part of the task is to develop appropriate levels of independence.

The Assessment Process

Assessment of most children will involve spending some time with the child, some time with the carers, and some time with them together and perhaps even some time with the wider family. All children should be afforded some time alone and the extent of this will be influenced by their age, level of cognitive functioning, and the nature of their presentation. Some clinicians recommend starting with the family together and then giving each party some time alone. My own experience has led to a different approach. With older adolescents (age 14 years upward), I usually offer the young person the opportunity to start with me alone to emphasize that I value their perspective and second I have found that parental presence can limit the child's input to the assessment process.

It is likely that most children and families will have limited information about what child psychiatry services do; so it is probably helpful to provide an information leaflet such as the one shown in Table 1. This has clearly been written from a 'Western UK perspective' and the information may not be the same across different contexts but the need to be clear about what the service does and how it functions is relevant whatever the context.

As in other services, professionals need to be aware that the experiences children have had may make them suspicious of mental health services. Children may also have been given misinformation about who they are going to see by parents who do not want to upset the child. It is widely acknowledged that nonspecialist professionals often have a poor understanding of mental health and may not have discussed the referral in any degree of detail with the family. After introductions have been made, a useful opening question is to ask the young person (and anyone else present) what they anticipate will happen. It is important to explore where they have obtained these ideas from, as their sources may be unreliable. Young people need to know that they are not being negatively judged and that they are valued.

The principles of engagement, respect, and such are as important and relevant in child psychiatry as in all other areas where human communication is a key part of the process. There is, however, an issue that in different contexts respect means different things to different people. It is best not to rely on stereotypes to consider what might be important to any particular child or family, but to discuss this at an individual level. Children who come from families where parents are authoritarian (and this can be from any cultural background) or backgrounds in which children are seen but not heard may be less forthcoming. Clinicians need to be open to the idea that children may need different levels of coaxing. Just because a child does not say much, does not mean he or she does not have anything to say. It is worth paying attention to the contexts. Exploring the meanings of mental health for the child and the family is important, as this will reveal so much about their understanding and the work that lies ahead for everyone. At the same time, it is important to avoid making assumptions or trying to explain things in a way that supports one's own world view.

Diagnosis and Management

Diagnosis should use either the International Classification of Diseases or the DSM. The treatment approach is guided by the assessment and should always be discussed with the child and family, as their knowledge, consent, and motivation are essential if the treatment is to be successful. In planning treatment, the setting, the content, and the method of the treatment should again be considered. Additionally, the mode of treatment should be considered. The setting may again be in the family home, general practitioner surgery, local child psychiatry clinic, or pediatric liaison clinic.

The content of treatment can again be divided into psychological, environmental, biological, or developmental. Each of these should be taken into account when deciding on the method of treatment, which may be individual therapy, work with parents/carers, group therapy, family therapy, drug treatment, or a combination of these. The mode of treatment in child psychiatry is commonly behavioral, psychodynamic, cognitive, educational, supportive, or a combination of these. Each mode of treatment can be applied in at least one of the methods of treatment. However, it is usually best to consider each treatment method in turn: individual therapy, parent work, group therapy, family therapy, and drug treatment. Most therapies in psychiatry can be used in children and adolescents but will require adaptation for use with particular groups or may not be suitable for them (e.g., very young children and individuals with severe learning disabilities). Basic parenting work can usually be delivered by other agencies whilst family therapy and family work is more likely to take place within CAP although not exclusively limited to CAP services.

Summary

In summary, although a relatively young specialty, CAP has made significant advances and there are clear principles of good practice. While there have been advances in understanding

Table 1 Child and Adolescent Mental Health Service information leaflet for first appointment (to be sent with appointment letter)

What is a Child and Adolescent Mental Health Service?

A Child and Adolescent Mental Health Service (CAMHS) is a specialist service that offers assessment and treatment for child mental health problems. We generally see children and young people up to the age of 18 years.

What is a mental health problem?

Children and young people can experience a range of emotional, psychological, behavioral, and psychiatric problems for which specialist help is required. A mental health problem can be seen as a problem that affects the child or young person or their family and prevents them from achieving their potential. Not all child mental health problems need specialist services but those that are complex, severe, or persistent benefit from such involvement.

Examples you may have heard of include depression, anxiety, attention deficit hyperactivity disorder, autism, or family problems.

Child mental health problems are rarely caused by a single factor and it is usually a combination of individual, family, social, and environmental factors that lead to problems.

Who will you see?

There are many different types of professionals who work in CAMHS. They include

Doctors (specialized in child psychiatry)

Nurses

Psychologists

Therapists trained in a variety of treatment strategies such as psychotherapy, art, cognitive behavior, and family

Our staff are trained in working with children, young people, and their families to ensure that the service we provide is tailored to your needs using the best evidence there is. We are committed to working together with you so that any interventions offered are appropriate and acceptable to you and your family.

Who needs to come?

For the first appointment, we suggest the carers come along with the young person who has been referred. You are also welcome to bring other family members, a friend or an advocate if you feel that would be helpful to you.

If we need to make any special arrangements such as access, please let us know before coming as we want to make your visit as comfortable as we can.

What will happen when you come to see us?

When you attend your first appointment, we will ask you to complete some forms. It seems like a lot of work but it is really important to us that we understand your point of view. You will then be seen by one or two clinicians and the appointment lasts between one and one and a half hours.

Depending on the young person's age, some of the assessment may be done with the young person and the carers together and part of it with them separately. This is so we can understand everyone's point of view to better work with you in planning any further care. The appointment is quite long because we need to collect quite a lot of information to be able to make a thorough assessment.

After the first meeting, the clinicians will feedback their assessment to you and there may be one of several outcomes:

- No further assessment or treatment required and the person is discharged from the service.
- Further assessment is required; so more appointments are made.
- A diagnosis is made and suggestions for treatment options are discussed. Treatment may be offered immediately or the young person placed on a treatment waiting list dependent on the issues.

Whatever the outcome, the clinicians will discuss this with you to ensure that your views have been taken into account. The clinician will write to the person who asked you to come and see us and you will get a copy of the assessment letter.

You should know that we are happy to be asked about what we do as it is important for us that you are as fully informed as is right for your development about your own care.

Confidentiality

We offer a confidential service but there are times we need to share information with partner agencies to ensure we deliver the best care that we can. If we plan to share information about you we will ask for your or your carers' permission unless there are concerns for your safety in which case we are legally obliged to share information to ensure your protection. For young people, it is important to know that they can share information with clinical staff that is just between them. Again, information will be shared with parents only in cases where there are concerns for your safety.

How to find us?

We are based at Westcotes House on Westcotes Drive, Leicester.

the etiology and treatments available, there is still much to be done in identifying the relationship between treatment and outcomes.

Child Care and Child Development

AC Huston, University of Texas, Austin, TX, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Most children in modern industrialized societies will spend a significant portion of their early lives in child care, and many will require such care during the early school years as well. Initial fears that child care per se would be harmful have not been supported, but there is some evidence that extensive care, beginning in early infancy, can make it more difficult for mothers to relate sensitively to their infants. Whether child care has positive or negative effects on children's development depends primarily on its quality. Quality is defined by sensitive, responsive, and stimulating caregivers and age-appropriate activities and curriculum. High-quality care promotes cognitive, academic, and social development, and its effects last beyond the preschool years. Children attending child care centers as opposed to home-based child care perform better on language and academic skills and have skills with peers, but are also more aggressive and noncompliant.

Most children in modern industrialized societies will spend a significant portion of their early lives in child care, and many will require such care during the early school years as well. Initial fears that child care per se would be harmful have not been supported, but there is some evidence that extensive care, beginning in early infancy, can make it more difficult for mothers to relate sensitively to their infants. Whether child care has positive or negative effects on children's development depends primarily on its quality. Quality is defined by sensitive, responsive, and stimulating caregivers and age-appropriate activities and curriculum. High-quality care promotes cognitive, academic, and social development, and its effects last beyond the preschool years. Children attending child care centers as opposed to home-based child care perform better on language and academic skills and have skills with peers, but are also more aggressive and noncompliant.

Child care is regular care provided by someone other than a child's parents. Throughout human history, grandparents, siblings, and relatives have cared for young children, but since about the 1950s, nonparental child care has become an increasingly visible and prevalent part of the lives of young children in most industrialized societies, largely because of increasing rates of maternal employment and of single-mother families. In the United States, by 1997, the majority of infants and preschool children spent some time in child care; many of them were in full-time care (35-plus hours per week) (Capizzano and Adams, 2000).

This rapid and dramatic change in the ecology of children's experience has raised a host of questions about the benefits and risks associated with nonparental child care. Strong value commitments and assumptions have often influenced the questions asked. In the first wave of research in the 1970s, for example, researchers asked whether 'day care' was harmful to children; they rarely considered potential benefits. At the same time, others were investigating the benefits of 'early childhood intervention' without considering possible harmful effects. Both groups were examining systems of nonparental care for young children, but the ways they framed questions and the labels they used led to different conclusions.

Is Extensive Child Care Harmful?

Why might we expect nonparental child care to be harmful for children? According to the 'maternal deprivation' view, having one primary caregiver (usually the mother) with whom to develop an early attachment relationship is critical to the socioemotional development of young children. This view implies that even very high-quality nonmaternal care could impair the development of a secure attachment to the mother, if it seriously reduced the amount of time that a child spends with its mother. The most commonly used measure of attachment is the Strange Situation, a laboratory procedure in which children are observed during and after brief separations from their mothers. Secure attachment is indicated when the child goes to the mother and is comforted by her. Insecure attachment may be manifested by avoiding or ignoring the mother or by clinging to her without being comforted.

A large number of early studies concluded that child care in the preschool years did not have harmful effects on attachment security or later socioemotional development, but the evidence is more mixed with respect to extensive nonmaternal care in the first year of life. Although the majority of children who receive full-time child care in infancy have secure attachments to their mothers, some studies find elevated rates of insecure attachment when comparing these children to those in exclusive maternal care or part-time child care (Bystrova et al., 2009). A major study of 1153 infants across the United States indicated that children who spent extensive time in child care during the first 3 years of life had mothers who were slightly less sensitive in interactions with them, and that extensive care was associated with elevated rates of insecure attachment only for children whose mothers were insensitive (NICHD Early Child Care Research Network, 1997, 1999a,b). As one reviewer concluded, "Adverse effects on infant-mother attachment appear to occur only when infant day-care co-occurs with other risky conditions, …" (Lamb, 1997; Lamb and Ahnert, 2006).

It does not appear that time in child care, in and of itself, has long-term effects on most other aspects of socioemotional development, but children with extensive care from infancy on tend to be more aggressive and assertive and to be less compliant to adults in some settings than are those with less

child care experience. Many of these differences are not apparent when children have experienced high-quality care (Lamb and Ahnert, 2006).

Quality of Care

A second theory predicts that the effects of child care depend on the physical and social environment provided. Harmful effects on both social and intellectual development might be expected if children receive less attention, affection, interaction, and stimulation from nonparental adults than they would from their parents. This view implies that the effects of care depend on its quality and on the quality of the home environment. Quality can be defined by the processes that occur in the setting: (1) sensitive, responsive, positive interactions of adults with children; (2) intellectually stimulating adult actions and activities, including appropriate language, reading, and play; and (3) toys, materials, and curricula that provide age-appropriate opportunities for learning. Quality can also be defined by structural characteristics, some of which can be mandated by regulatory agencies: (1) small ratios of children to adults; (2) small group sizes; (3) caregiver education and training in child development; (4) sufficient space per child; (5) a safe and clean physical environment; and (6) continuity and wages of the staff. Structural and process measures are correlated moderately with one another.

Whether process or structural indicators of quality are used, children in high-quality care have higher levels of language and intellectual skills, and perform better on academic tasks than do children in low-quality care. Although this finding is consistent across studies, there is some disagreement about whether quality produces a large enough difference to be socially significant (Lamb and Ahnert, 2006; Vandell and Wolfe, 2000). In one analysis, the quality of the child care environment and characteristics of the home environment during the first 3 years of life were compared as predictors of school readiness and language skill at age of 3 years. The size of the child care quality effect was about half that of the family environment, suggesting that child care makes a substantial contribution to language and academic development (NICHD, 1999a,b). Critics have also argued that child care effects do not last into later childhood, but evidence for long-term effects is beginning to accumulate. In a large study following children from age of 4 years through grade 3, children who attended higher quality child care centers performed better on measures of cognitive skills (e.g., math and language abilities) while they were in child care and, in many cases, through the end of second grade (Currie, 2001).

High-quality child care also predicts social skills with peers and social competence with adults, but the relations between quality and social behavior are weaker than those between quality and cognitive/academic performance. Some studies suggest that children's relationships with their teachers in child care forecast social skills and relations with teachers in elementary school (Ahnert et al., 2006, Currie, 2001).

One problem in evaluating child care effects is that families with more resources, better education, and more sensitive parenting styles (to name only a few attributes) place their children in higher quality child care settings than do less advantaged families. Most recent studies have measured both family and child care characteristics so that the independent contributions of each could be evaluated, but there is still the possibility that other unmeasured family attributes could affect child care choices and children's cognitive and intellectual development.

Experimental studies, in which children are assigned randomly to enriched early care experiences or to control groups, demonstrate clearly that high-quality early care has lasting effects on cognitive and academic skills, at least for children from economically disadvantaged families. Experiments avoid possible confounds between family and child care attributes. The Abecedarian project enrolled children from low-income families in educational child care from infancy until they reached school age. Children in the treatment group performed better than children in a control group (who received social and nutritional services) on tests of intelligence and school achievement throughout childhood and adolescence (Ramey et al., 2000). Less-intensive early intervention programs for children aged 3–5 years also produced lasting effects on children's school progress; participating children were less likely to be retained in a grade or to need special education than were children in control groups (Reynolds et al., 2001).

The importance of child care does not end when children enter school. Participation in formal after-school care programs that provide cognitive stimulation and positive adult interactions is associated with high academic achievement and low levels of behavior problems, particularly among low-income children (Mahoney et al., 2005). Children without adult supervision in the out-of-school hours are at risk for behavior problems and poor adjustment, particularly if they live in low-income families or unsafe neighborhoods (Pettit et al., 2001).

Type of Care

A great deal of child care occurs in the child's home or someone else's home, especially for infants and toddlers. Caregivers can be grandparents, other relatives, or nonrelatives. In the United States, a small percentage of infants receive center-based care, but the percentage increases as children reach ages 3–5 years. Many western European countries have extensive center-based care for children aged 3 years and over, but care settings for younger children vary considerably (Waldfogel, 2001). The available data suggest both advantages and disadvantages of center-based care relative to home-based care for very young children. Infants and young children in center care show better language and cognitive development by ages 2 and 3 years than those in home-based settings of comparable quality, but they also have more communicable illnesses (e.g., colds and other respiratory illnesses) (NICHD, 2000).

Children attending a center or a child care home with several other children have more experience with peers than do children in other types of home-based care. Children with extensive group experience develop better skills interacting with peers, but their caregivers also rate them higher on negative behavior (e.g., aggression, disobedience) than

children in other forms of care (Lamb and Ahnert, 2006). For young children, social skills and sociability with peers are often accompanied by a certain amount of aggression; perhaps early contact with peers leads to increases in a range of social behaviors.

Do Effects Differ for Children from Different Family Backgrounds?

In the United States, where most child care is funded privately, children from affluent families receive higher quality care than children from families with low and moderate incomes do. In some cases, children from very poor families receive slightly higher quality care than children from families with modest incomes, largely because of publicly funded programs for children in poverty (Johnson et al., 2003). In countries with publicly funded child care for children from all income levels, average quality appears to be considerably better than it is in the United States, and there are not wide discrepancies in quality associated with family income (Lamb and Ahnert, 2006).

Some researchers have proposed a compensatory hypothesis: children from disadvantaged homes might profit from child care of reasonable or high quality because it provides more opportunities for learning and development than they receive at home. The complementary lost resources hypothesis suggests that children from highly advantaged homes may be harmed by child care because it provides fewer opportunities than their home environments do. The evidence for these hypotheses is mixed. Almost all of the experiments exposing children to high-quality care have included only economically disadvantaged children, and these children clearly profit from such care. Some investigations have found support for the lost resources notion, but most studies support the idea that high-quality care provides benefits for children from a wide range of backgrounds (Lamb and Ahnert, 2006).

Public Policy Issues

Public versus Private Funding

Child care is expensive. In some industrialized nations, public funds pay the great majority of the costs. Sweden, France, and some other countries provide large-scale publicly funded, full-day, preschool programs. In the United States, at the other end of the spectrum, limited amounts of public funds are available to low-income families, and tax credits cover a small portion of child care costs for people earning enough to owe taxes. Overall, parents pay the vast majority of the costs of care. At the same time, child care workers and staff receive very low wages. In 1997, teachers in child care centers, many of whom had college degrees, earned from approximately $13 000 to $19 000 per year; salaries of teaching assistants ranged from $10 500 to $12 250 per year (Whitebrook et al., 1998). As a result, there is high turnover among child care workers.

Family Leave versus Infant Care

Care for infants is more expensive than care for preschoolers because they require more concentrated adult attention and they fare best in small groups. Many industrialized nations provide parents with paid family leave as an alternative to supplying center-based infant care (Waldfogel, 2001). In the United States, some workers receive paid family leave, but federal law requires only that parents receive up to 12 weeks of unpaid leave with guaranteed job security and medical benefits. Even this policy applies only to full-time, full-year workers in large organizations. As a result, many infants enter nonmaternal care between ages 2 and 3 months. There is some evidence that mothers who return to work very early and whose babies have extensive nonmaternal care are less sensitive during interactions with their infants than are mothers who have more time at home (Bystrova et al., 2009). It may be more difficult to learn your infant's signals and respond appropriately when you spend a great deal of time at work starting very early in the child's life.

Conclusion

Most children in modern industrialized societies will spend a significant portion of their early lives in child care, and many will require such care during the early school years as well. Initial fears that child care per se would be harmful have not been supported, but there is some evidence that extensive care, beginning in early infancy, can make it more difficult for mothers to relate sensitively to their infants. Whether child care has positive or negative effects on children's development depends primarily on its quality. Quality is defined by sensitive, responsive, and stimulating caregivers and age-appropriate activities and curriculum. High-quality care promotes cognitive, academic, and social development, and its effects last beyond the preschool years. High-quality care for children from all economic levels is provided more successfully in countries that make large public investments in early care than in countries that require parents and child care staff to pay the costs of care.

Future Directions

Nonmaternal care is here to stay. Policy debates about what is 'good enough' care abound, and research is needed to identify thresholds of quality that make large differences, with particular attention to individual child and family characteristics. We understand how early child care can contribute to cognitive and academic performance better than we understand how it can influence positive social behavior with both peers and adults. New designs, including experiments with random assignment, could help to answer these important questions.

Child Care and Development across Cultures

Birgit Leyendecker, Ruhr University Bochum, Bochum, Germany

Abstract

Every culture has found unique solutions for the universal task of raising healthy children. These solutions may be adaptive and adequate in one cultural context yet they may appear inadequate in another context. Thus, there is no one single right way but rather multiple cultural pathways to children's well-being and healthy development both within and outside of the family. While mothers are the primary caregivers of infants in basically all cultures, the social context in which these relationships are embedded as well as the role of professional caregivers varies greatly.

Tom Weisner (1996) described what happens when he asks students and colleagues about what they consider to be the single most important influence on children's development. The answers are predictable, for example, to provide a safe socioemotional environment, nutrition, medical care, education, etc. As Weisner points out, almost no one comes up spontaneously with what he considers to be the single most important influence: the culture in which a child develops and matures. Whether a child grows up in rural Arkansas or in downtown San Francisco, on a tiny island in the North Sea or in the Amazon rainforest, in Singapore or in a township in South Africa is going to greatly influence his development, the abilities and skills he is going to acquire, and his perception of the world. Culture includes the shared knowledge and shared meaning (cultural interpretation) as well as shared practices that are transmitted and transformed over the generations.

Variations of childrearing practices within a culture are influenced by features such as education, social and economic resources, size of the family, and urban or rural living environment (Keller, 2013). Thus, childrearing practices and the parental ethnotheories are adapted to the resources of a family as well as to the cultural habitat. This has implications for the study of caretaking arrangements and children's development in diverse cultural niches. Childcare practices that may appear meaningful and may make sense in one cultural habitat may appear inadequate and senseless in another habitat (Keller, 2013). Therefore, research on early childcare and parenting practices are presented with the challenge of disentangling cultural effects on children's development from the environmental features and the resources available to families.

The acknowledgment of "the startling, disturbing, wonderful variety of what it means to be a child or parent and the variety of forms development can take" (Weisner, 1996: p. 306) has challenged the conception of the universal child and has shifted the focus to understanding the "child in context" (Bronfenbrenner, 1979). Super and Harkness (1986) have developed the concept of the developmental niche as a framework to understand how culture influences the organization of the developmental environment and thereby affects the course of development. A developmental niche is conceptualized by three interacting subsystems: the physical and social settings of a child's everyday life, the customs of childcare and childrearing, and the psychology of the caretaker. These subsystems account for similarities across developmental niches due to similar influences. Childcare and childrearing practices are, for example, associated with other customs in the child's developmental niche that have proven to be successful and adaptive. Each generation of parents is likely to modify childrearing practices according to their needs, yet instead of reinventing the wheel anew in each generation they are likely to build their childcare practices on the cultural practices of previous generations. These subsystems also account for differences and variability in relationships between children's development and their environment. For example, variability may result due to the personality of the parents and their individual resources or the children's gender and temperament (Super and Harkness, 2002).

Culture Matters in Human Development

Despite the enormous variety of developmental niches and the customs of childcare and childrearing within these niches, there is at least one overarching similarity: Regardless of their cultural background, all parents want to foster their children's healthy development. They want them to survive and to thrive, to grow up to function well in their everyday life, to become well adjusted, responsible members of the society who get along with others, can comply to rules and authority, and who are able to provide for themselves economically. What constitutes a responsible member of the society, what is meant by providing for oneself, and how these goals can be achieved may differ greatly both within and across cultures (Keller, 2013; Leyendecker et al., 2002). Accordingly, Keller (2013: p. xiii) describes the "developmental pathways as cultural solutions for universal developmental tasks." These developmental pathways and associated childrearing practices are not static but are likely to change gradually (or rapidly) over time as sociodemographic ecologies change and cultural values are adapted accordingly (Greenfield, 2009).

In her research, Rogoff and her colleagues (Rogoff et al., 1993; Rogoff, 2003) have addressed the question of how culture matters in human development, and how children acquire knowledge relevant to their sociocultural niche. Rogoff (2003) differentiates between child-focused activities and children's participation in mature activities in their community. Children's participation in adult activities requires children to observe the ongoing activities. Adults or older children

may facilitate and support their participation. In contrast, structured child-focused activities require that an adult caregiver provides the learning opportunities and structured teaching situations, e.g., teaching a child how to insert wooden blocks of different shapes into a box with openings that match these shapes. Parents in Western cultures who are more likely to provide child-focused activities are also more likely to provide a daily schedule for their infants and young children with fixed times for sleeping, napping, and eating, and more opportunities for dyadic one-on-one interactions (Leyendecker et al., 1995). In contrast, children in non-Western cultures are more likely to participate in shared activities with the members of their community, their daily schedule is likely to be centered around an individualized schedule, and they are likely to have more opportunities for interactions with multiple members of their family and other people who make up their daily social environment (Leyendecker et al., 1995; Rogoff, 2003). All developmental niches include participation in adult activities, guided participation, and specialized child-focused activities, yet the likelihood that children are presented with these different learning opportunities is likely to vary across developmental niches.

Cultural Variability of Caretaking Arrangements: Mothers and Others

From a psychological perspective, the quality of children's relationships with their parents and nonparental caregivers, as well as the availability of adequate economic, social, and physical resources are likely to promote children's healthy development and adjustment (Lamb, 2012). Once the enormous variety of cultures is taken into account, it becomes evident that there is no single best pathway to foster children's well-being, healthy development, and adjustment. Instead, there are as many pathways as there are different cultures in which children are raised (Greenfield et al., 2003; Keller, 2013). Especially in early childhood, the caretaking arrangements have been at the center of numerous debates on what is considered appropriate for children's healthy development. Keller (2013) criticizes that Western developmental psychology has adopted the norm that infants form an attachment bond primarily to the person they spend most of their time with – their mothers. She points out that from an evolutionary point of view as expressed by Hrdy (1999) "humankind would not have survived if solely mothers had been infants' caretaker" (Keller, 2013: p. 182). Instead, mothers and children benefit from alloparental help in childcare. Therefore, in line with Hrdy's (1999) work, she strongly advocates including mothers as well as others as potentially important caretakers and attachment figures in cross-cultural research on early child development.

Regardless of the cultural context they are born into, infants are likely to have their mothers as their primary caretaker in the earliest stages of life. Keller (2013) assumes that besides breastfeeding and nursing, other biological roots may foster this exclusive bond over the first 6 months of life. Aside from these similarities, the social environment the mother–infant pair is embedded in is likely to differ greatly. While differences between nuclear Western families and extended large non-Western families are most likely suitable to demonstrate the vast differences in social environments, variability within similar ecologies can occur as well. A study comparing the social environment of 10-week-old infants in diverse cultural settings in Europe, North and South America, and Africa found that with one exception, mothers were present or responsible for the child between 63 and 81% of the time the infants were awake (Schölmerich et al., 2002). The one exception was mothers of the Ngandu people in Central Africa. Interestingly, the two African samples from the Central African Republic – Aka and Ngandu – live in close proximity to each other and they can be described as traditional, small-scale, preindustrial, and non-Western (Berry et al., 1986; Hewlett et al., 2000). These two culturally distinct groups live in the same tropical forest yet their patterns of childcare vary greatly. The Aka are foragers (hunter-gatherers) who move their camps several times a year, have a high gender egalitarianism with men and women contributing equally to subsistence. In contrast, the Ngandu are sedentary farmers, have marked gender inequality with women receiving less although they are the primary providers and in charge of working the fields. When mothers were working in the fields, they were within earshot of their infants; however, older siblings were likely to be in charge. While both Aka and Ngandu mothers held their infants frequently, the Aka mothers were twice as likely to carry their infants and to be in constant body contact, and fathers were more likely to be involved in childcare (Hewlett, 2004; Schölmerich et al., 2002). While the social environment of infants in these two groups is markedly different, they still have more opportunities for interactions with multiple caregivers in a group setting when compared to infants growing up in a typical Western urban environment.

In her book *Cultures of Infancy*, Keller (2013) describes that while in basically all cultural environments mothers are the ones who are most likely to be in charge and responsible for the infant, differences lie in the social context – the amount of time siblings, kin, and others are in proximity and potentially involved. Keller (2012) argues that this contextual variability is largely ignored in attachment research and that the so-called Strange Situation developed by Ainsworth and her colleagues (Ainsworth et al., 1978) is suitable only for children growing up in an urban Western environment. While Keller recognizes the importance of the child's mother, she argues that a culturally sensitive attachment theory has to take the role of the social context into account as well. In a social context with many other caring adults or siblings present and involved, the mother–child relationship may be less exclusive as the child is used to be taken care of by others. Thus, these children are less likely to be distressed when their mothers are not present and more likely to allow other adults to pick them up and take care of them (Keller, 2012, 2013).

Conversely, Lamb (2012) criticizes the idea that the role of the biological mother is considered to be essential to children's well-being while all other potentially important attachment figures and caretakers are largely ignored. He states that relatives and nonrelatives alike, regardless of their gender, are able to take care of both younger and older children. In Western societies, the traditional family with two biological parents is more often replaced by a large variety of nontraditional families. Lamb (2012) argues that parents' capacity for good

parenting does not depend on their gender and that single-headed households as well as nonbiological parents do not put children at risk. Instead, availability of competent, caring, and nurturing adults, in conjunction with the availability of sufficient social and financial resources, contributes to the outcome of children in traditional and nontraditional families alike.

Early Childhood Education and Care by Professional Caretakers

In the first part of this article, the focus was on the enormous cultural variability of early childcare arrangements in diverse cultural niches. While mothers are the primary caretakers in almost all cultures, the social context in which these relationships are embedded may differ greatly. In addition, relatives and nonrelatives are likely to play an increasingly important part as the infants grow older. In the final part of this article, the focus shifts to the organized nonrelative caretaking arrangements, which are available, for example, in Europe and North America. Formal childcare arrangements differ greatly from the informal childcare arrangements with relatives or others who share either the same household or live in close proximity. Aside from live-in caretakers, most childcare arrangements with professional caretakers take place outside of the family in a separate building with little or no contact between parents and children during this period. This has raised much concern among parents and psychologists. Here, the question will be addressed whether nonparental formal childcare is beneficial for young children and whether qualitative nonparental childcare is available and accessible for families from all socioeconomic strata.

Despite great advances in research on early childcare, such as the NICHD Study of Early Child Care (e.g., NICHD Early Child Care Research Network, 2002), there are still many open questions. Is nonrelative childcare of toddlers a source of enrichment that promotes cognitive and linguistic development or is childcare at this young age associated with developmental risks? Can high-quality childcare counterbalance low-quality care in the home environment? Should we encourage families to enroll their children at a young age in a nursery school? In the United States, Canada, and some parts of Europe, many small as well as several large-scale studies have addressed these questions. While findings based on research on the relationship between quality and especially quantity of early childcare on social skills and externalizing behavior problems are mixed (e.g., Loeb et al., 2007; Love et al., 2003; Vandell et al., 2010), there is general agreement about the association between high quality of childcare and children's advanced cognitive and linguistic functioning (Belsky, 2006; Love et al., 2005; NICHD ECCRN, 2002; Ruzek et al., 2014). These effects were still visible during middle childhood and adolescence. Children attending high-quality childcare were found to receive higher scores on tests of math, reading achievement, and memory in elementary school (NICHD Early Child Care Research Network, 2005), and higher scores on cognitive academic achievement later in adolescence (Vandell et al., 2010). An analysis of the Early Head Start program in the United States found significant gains in cognitive and language functioning in 2- and 3-year-old children from low-income families enrolled in high-quality programs (Love et al., 2003). Burchinal et al. (2000) who analyzed data from three large childcare studies found support that the quality of childcare is related to developmental outcomes of all children regardless of their social risk status. For minority children, however, the advantages of high-quality childcare appear to be most pertinent to their language development (Burchinal et al., 2000; Buysse et al., 2013).

Accessibility of Early childcare

As Belsky (2009) points out, children of all ages benefit from high-quality care relative to those experiencing poor-quality care. Ideally, nonparental care should be at least as stimulating as parental care (Ahnert et al., 2006). Nonparental caretakers, who are attentive to children's verbal and nonverbal signals, respond adequately, and provide a stimulating learning environment can foster children's development. Aside from the issue of quality of care, there is the issue relating to what extent children have access to nonparental care. In some countries, such as the Netherlands, Sweden, France, and Switzerland, early childhood education and care is mostly publicly funded for children from the ages of 3 or 4 years. In other countries, such as Germany, Norway, and Austria, early childhood education and care is publicly available but not free of charge. In Germany, for example, some municipalities offer childcare free of charge. Most families, however, have to pay for childcare before children start school. Even though these fees are quite low for low-income families, children from these families are less likely to attend nursery schools (for the ages 1–3) and are likely to enroll in the so-called Kindergarten (ages 3–6) at a later age (Leyendecker et al., 2014; Tietze et al., 2013) About one-third of all children in Germany have at least one immigrant parent. While immigrant families are from all social strata, they are most likely to have less financial and educational resources when compared to the German majority. They are less likely to be familiar with strategies on how to enroll a child into public childcare at an early age. In addition, relatives such as grandparents who may support parents are less likely to be available and involved when compared to nonimmigrant German families (Tietze et al., 2013).

In sum, children all over the world are likely to be cared for primarily by their mothers in the first 6 months of their life. Aside from this parallel, their social environment, however, is likely to differ greatly and influence their early experiences. Despite the great variety of developmental niches, there is general agreement that all children "thrive psychologically, when they are nurtured by caring competent parents who are themselves embedded in warm supportive relationships" (Lamb, 2012: p. 101). The parental role can be filled by the child's biological or nonbiological parents as well as competent older children or caring adults. In their first years of life, some children especially in Western cultures may be cared for primarily by their parents. Most children around the world, however, are likely to be cared for by parental and nonparental caregivers. These early experiences and the quality of care these caregivers provide are part of their diverse cultural pathways, and will influence children's development.

Child-Directed Speech: Influence on Language Development

Rupa G Gordon and Linda R Watson, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA

Abstract

Child-directed speech (CDS), or speech adjustments made by adults when interacting with children, is characterized by higher pitch, more repetition, simplified vocabulary, and exaggerated intonation patterns. Here, we review the role of CDS in enhancing language acquisition. Not only have strong global relationships have been found between maternal linguistic input and language development, but also specific features of CDS (e.g., higher pitch and exaggerated prosody) have been discerned that seem to assist in language learning. Finally, we review evidence from developmental disorders further support the relationship between CDS and language acquisition.

Introduction

Child-directed speech (CDS) refers to speech adjustments made by adults when speaking to children and infants. CDS differs from adult-directed speech (ADS) as it is characterized by higher pitch, greater pitch range, exaggerated intonation patterns, elongated vowels, shorter utterances, more repetition, more questions, simplified vocabulary, and less use of past tenses (Pine, 1994; Snow, 1977). In general, the characteristics of CDS are believed to serve many important functions, including (1) enhancing language acquisition, (2) gaining and holding the infant's attention, (3) developing the affective bond between infant and mother, and (4) facilitating social interaction and early communication (Sachs, 1977). Beyond speech, adults also make other modifications to their communicative behaviors during interactions with children, including the use of simplified gestures and exaggerated facial expressions and movements (Brand and Shallcross, 2008; Chong et al., 2003; Iverson et al., 1999; O'Neill et al., 2005).

Infants display strong preferences for CDS compared to ADS as early as 1 month of age (Cooper and Aslin, 1990), regardless of the speaker's gender (Pegg et al., 1992), and this preference continues through toddler (Kuhl et al., 2004; Paul et al., 2007) and preschool years (Klin, 1991). They also show increased neural responses to CDS compared to ADS as measured by Event-Related Potentials (ERP) (Zangl and Mills, 2007) and Near-Infrared Spsectroscopy (Saito et al., 2007). Furthermore, this difference in brain activity is greatest when the CDS is produced by the infant's own mother (Naoi et al., 2012). Infants also display strong social preferences for speakers who use CDS, suggesting that CDS plays an important role in the development of social bonds. Schachner and Hannon (2011) found that 5-month-old infants preferred to look at an individual who previously used CDS compared to a novel individual, and this preference is not found for individuals who used ADS.

The characteristics of CDS change as a function of the child's age and developmental abilities. Stern et al. (1983) found that CDS to neonates (2–6 days old) is characterized by long pauses, short utterances, and steady rhythms, as neonates require low levels of stimulation and social interaction. In contrast, at 4 months old, the child is much more active and the mother uses the most exaggerated features of CDS, including pitch and repetition. At 12 and 24 months, when the child is exploring independently and playing with objects, the mother facilitates the child's explorations by using speech that is more object focused, and CDS is characterized by longer durations of vocalizations and more complex utterances (Adamson and Bakeman, 1984; Stern et al., 1983).

The aim of this article is to review evidence that the modifications associated with CDS impact language acquisition. Note that although many studies have focused on maternal use of CDS and this article will reference maternal behaviors frequently, many of these findings are also applicable to fathers and other adults (e.g., Fernald et al., 1989; Jacobson et al., 1983; Papoušek et al., 1987).

Associations between Maternal Linguistic Input and Language Acquisition

Some early studies, notably the work of Newport et al. (1977) discounted the role of CDS in language acquisition because their findings suggested no relationship between the simplicity of maternal language and children's language acquisition. They argued that CDS might not be beneficial for language learning as its apparent simplifications often involve deletions that may make the content more difficult for the child to understand. Despite these early findings, current research has found strong associations between the use of CDS and language acquisition, and has also discerned specific characteristics of CDS that benefit language learners.

Multiple studies have examined the global relationship between maternal linguistic input and language acquisition using longitudinal correlational designs. Several aspects of maternal speech at 18 months, including utterance length and use of verbs and pronouns predicted characteristics of children's speech at 27 months, such as utterance length and verbs use (Furrow et al., 1979). Numerous studies have found that maternal linguistic input and vocabulary diversity are positively associated with vocabulary development (Hart and Risley, 1995; Hoff and Naigles, 2002; Huttenlocher et al., 1991; Weizman and Snow, 2001).

Furthermore, certain interactive features of early caregiver–child communication appear to promote language development. For example, children whose mothers engaged with them in more joint interactions, rather than directive

interactions, developed larger vocabularies (Tomasello and Todd, 1983), and maternal responsiveness to vocalizations at both 9 and 13 months predicted the child's achievement of certain milestones of expressive language, including first words, first 50 words, and first use of language about the past (Tamis-LeMonda et al., 2001). Although directive maternal utterances have been associated with poorer child language outcomes in numerous studies of typically developing children (e.g., Hampson and Nelson, 1993; Tomasello and Farrar, 1986), other research points to the need for more nuanced analyses of caregiver directiveness. For example, caregiver directives given when the caregiver and child share an attentional focus are associated with more positive child language outcomes in typically developing children (Akhtar et al., 1991; Masur et al., 2005). These findings collectively point to the potential benefits of providing language input that is responsive to the child's focus of attention rather than redirecting the child's focus. But this generalization also may be too broad. A recent study of low-income African-American mother–child dyads in the United States found that the number of directive object labels (i.e., labels for objects outside of the child's focus of attention) that mothers used was positively associated with the children's later vocabulary, whereas the number of responsive object labels (labels for objects within the child's focus of attention) was not (Shimpi et al., 2012). Thus, there remain considerable gaps in understanding the complexities of the relationships between CDS and child language outcomes, and the mechanisms accounting for these relationships.

It is critical to remember when interpreting the findings of these correlational studies that social interaction involves mutual and reciprocal influences from both interactants. Indeed, an important influence on the mother's behaviors and responsiveness are the infant's own behaviors. Behaviors such as smiling, crying, and infant vocalizations influence the mother's responsiveness and speech to the infant (Henning et al., 2005), as do more explicit uses of gestures (e.g., pointing) and infant sign language (Vallotton, 2009). Experimental manipulations of the feedback mothers receive from the infant also provide strong support for this idea. For example, when mothers interacted with their child via video, but the video feed of the infant was surreptitiously delayed, mothers tended to use more interrogatives than when it was truly live, suggesting that mothers are sensitive to important behaviorally contingent feedback cues from the infant (Murray and Trevarthen, 1986). Mothers also tend to raise their pitch when they receive positive feedback from the child (Smith and Trainor, 2008).

Identifying Features of CDS That Impact Language Acquisition

Correlational studies describing the relationship between CDS and language acquisition suggest a strong relationship, but it is difficult to parse out the specific influences of CDS. More recently studies have experimentally manipulated aspects of CDS in order to identify specific characteristics of CDS that can benefit language development. Research has shown that the impact of different features of CDS on language acquisition varies with the age of the child (Rowe, 2012). Indeed, CDS seems to be advantageous for language acquisition, particularly for infants and young children. In infants (7–8 months of age), long-term learning (delay of 24 h) only occurred for words presented in CDS compared to ADS (Singh et al., 2009). Similarly, 21-month-old children learned novel words better when presented using CDS rather than ADS, but by 27 months children learned words equally well in both conditions (Ma et al., 2011), highlighting the relevance of considering the child's age and language level as a factor in evaluating the impact of CDS on language acquisition.

Pitch and Prosody

The vast majority of research on the specific differences between CDS and ADS has focused on pitch and prosody. The higher pitch and exaggerated pitch contours of CDS serve multiple functions, including gaining the infant's attention, communicating intent and emotion, and supporting language acquisition.

The higher pitch of CDS is ideal for gaining the infant's attention because the fundamental frequency of CDS is typically within 400–600 Hz, falling in the optimal orienting range for infants (500–2000 Hz) (Sachs, 1977). ADS, on the other hand, typically falls within a lower, less salient range (e.g., 220 Hz for a woman; Sachs, 1977; Trainor and Desjardins, 2002). The prosodic patterns of CDS seem to convey communicative intent better than ADS, as adults are able to identify the speaker's intent with higher accuracy in CDS compared to ADS (Fernald, 1989). In fact, even non-English speaking adults from a nonindustralized, nonliterate culture are able to infer intentions from English CDS better than ADS, suggesting that there are universally recognized prosodic cues in CDS (Bryant and Barrett, 2007). The pitch height and exaggerated pitch contours of CDS also enhance the vocal expression of emotion, and therefore may support the development of affective bonds between mother and child (Trainor et al., 2000).

The pitch and prosody characteristics of CDS also serve other functions that may assist in language acquisition. Prosody in CDS may facilitate speech processing by highlighting and emphasizing target words, whereas prosody in ADS is more variable and less likely to highlight target words (Fernald and Mazzie, 1991). The exaggerated pitch contours of CDS are beneficial for discriminating and learning vowel categories (Trainor and Desjardins, 2002; Vallabha et al., 2007), as well as syntax, as it contains a greater number and more reliable markers of major syntactic units than ADS (Nelson et al., 1989). Prosody in CDS facilitates word segmentation from fluent speech, evidenced by infants' ability to distinguish words from nonsense sentences when the sentences exhibit the intonation patterns and structure of CDS rather than ADS (Thiessen et al., 2005). Finally, a prospective study found that 20 month children who heard CDS that was characterized by reduced prosodic stress on target words and less varied prosodic contours had reduced vocabulary development at 24 months, suggesting that the lack of prosodic stress in CDS potentially impaired the child's ability to segment and highlight target words (D'Odorico and Jacob, 2006).

Other Features of CDS

There are multiple characteristics of CDS beyond prosody and pitch that contribute to language acquisition. The simplicity and repetitive nature of CDS is believed to serve the purpose of reducing confusion and enhancing gains in language acquisition (e.g., Snow, 1977 but see Newport et al., 1977). Specifically, the frequency with which mothers use words impacts the acquisition of vocabulary (Goodman et al., 2008) and the frequency with which words are spoken in isolation (i.e., not as part of a fluent speech stream, a common occurrence in CDS) predicts acquisition better than the total frequency of exposure in a naturalistic longitudinal study (Brent and Siskind, 2001). Similarly, exposure to words in isolation as well as in fluent speech enhanced infants' learning of statistical properties of words in an experimental study, whereas exposure to the words only in fluent speech alone did not (Lew-Williams et al., 2011). Furthermore, the variability with which a word is presented (i.e., used by multiple speakers in multiple contexts) also positively influences word recognition and generalization (Singh, 2008). The phonetic units of CDS are altered so that the vowel space is expanded compared to ADS, such that vowels are clearer, longer, and more distinct from each other (Kuhl et al., 1997). Moreover, the manner in which the phonetic cues to distinguish vowels are altered in CDS is language specific. Japanese mothers alter the phonetic cues that are more relevant for vowel discrimination in Japanese, while English mothers alter those cues that are more relevant for vowel discrimination in English (Werker et al., 2007). Word segmentation in multiple languages is also facilitated by the use of diminutives (e.g., doggie, Stevie) by increasing invariance in word endings and stress patterns (Kempe et al., 2007).

Extralinguistic Features of Child-Directed Communication

Recent research suggests that adults make other communicative alterations when talking to children beyond changing the characteristics of their speech (Iverson et al., 1999; O'Neill et al., 2005). Gestures are more concrete and simplified when used with children. Gestures such as pointing and showing were used more often to support speech and disambiguate and emphasize verbal references (Iverson et al., 1999; O'Neill et al., 2005). Furthermore, emphatic or beat gestures that are common in ADS, such as making circular motions with a flat hand while speaking, are not typically found in CDS (Iverson et al., 1999; O'Neill et al., 2005).

Other aspects of the interaction tend to be exaggerated, such as movements and facial expressions (Green et al., 2010; Stern, 1974). Distinct facial expressions have been found in infant interactions of both English-speaking and Chinese-speaking mothers that are not typically found in adult interactions (e.g., mock surprise, pursed lips) (Chong et al., 2003). Mothers also modify their movements, termed motionese, in order to enhance attention and to highlight aspects of the movement and concurrent speech (Brand and Shallcross, 2008; Rutherford and Przednowek, 2012). Specifically, Brand et al. (2002) found that when mothers demonstrated novel objects to their children vs to an adult, they used more exaggerated movements, displayed more enthusiasm, and used movements that were simpler, larger, and more repetitive. Furthermore, infants preferred watching motionese compared to movements produced in adult-directed interactions (Brand and Shallcross, 2008; Koterba and Iverson, 2009) and infants spent more time engaged with those objects for which the adults used more repetition in their movements (Koterba and Iverson, 2009).

Mothers also integrate the use of multiple modalities when talking to children, which positively influences language learning. The presentation of visual information (e.g., moving or manipulating an object) closely synchronized with auditory information from speech increases the saliency of the target. This type of temporal synchrony is used to highlight novel word-referent relationships, and children spend more time attending to targets and show better learning of new words (Gogate et al., 2000, 2006).

Necessity of Social Interaction

Exposure to speech spoken using the characteristics of CDS may not be enough to influence language learning; rather, at least for infants, the ability to learn language also requires social interaction. Nine-month-old American infants were exposed via either live sessions or video recordings to Mandarin spoken using CDS over 12 sessions in which the speaker read books and played with toys. Only those children who had been exposed to the live sessions were able to learn a phonetic contrast that only occurs in Mandarin (Kuhl et al., 2003). The authors suggest that social and referential cues found only in live interactions, such as shared gaze and joint attention, may be critical for language learning.

Furthermore, social interaction also impacts the development of the production of speech and babbling in infants. Adult behaviors in response to infant vocalizations such as speech, smiling, and touching increases the production of infant vocalizations (e.g., Bloom et al., 1987; Ramey et al., 1972). Goldstein et al. (2003) found that adult contingent responses to 8-month-old infant vocalizations not only increased the frequency of vocalization, but also increased the proportions of vocalizations that had more developed voicing, syllable structure, and faster consonant–vowel transitions compared to baseline. Furthermore, when adult contingent behavioral responses were vocalizations, the infants altered their babbling according to the phonological patterns of the adult's speech (Goldstein and Schwade, 2008).

Universal Nature of CDS

If CDS is important for language acquisition, then these modifications should be found across languages and cultures. Indeed, modifications of speech for children are highly universal. Many of the characteristics of CDS, including shorter utterances, longer pauses, and expanded pitch contours, occur in cultural linguistic contexts that include native speakers of American English, British English, French, Italian, German, Japanese, and Mandarin (Fernald et al., 1989; Grieser and Kuhl, 1988). Although there are differences in the exact features of CDS across languages (e.g., Pye, 1986), and the degree to which

modifications of certain features occur (e.g., alterations in prosody are more pronounced in American English than other languages to which it has been compared (Fernald et al., 1989)), caregivers across virtually all cultures display modifications when speaking to children.

Child-directed alterations also occur in sign language. Masataka (1992, 1996) found that compared to when signing with adults, deaf mothers signed slower and used more repetitions and exaggerated movements when signing to their deaf infants. The infants also spent more time attending to child-directed signs compared to adult-directed signs.

CDS and Language Acquisition in Developmental Disabilities

Alterations in CDS to children with developmental delays in language acquisition lend further support for the relationship between CDS and language development. Compared to mothers of typically developing children of the same chronological age, mothers of children with Down syndrome produced more simplified speech, including fewer nouns (Cardosomartins et al., 1985), reduced syntactic complexity (Buium et al., 1974), exaggerated prosody (Fidler, 2003), and less complex gestures and combinations of gesture and utterances (Iverson et al., 2006). Mothers with children with autism spectrum disorder (ASD) modified their speech based on the level of functioning of their child, such that mothers of children with higher functioning verbal skills asked more questions, answered more questions, and reinforced the use of language, while mothers of children with lower functioning verbal skills used more directives, shorter utterances and reinforced the child's motor actions (Konstantareas et al., 1988).

Some argue that these modifications signify that mothers are sensitive to their child's developmental state (e.g., Konstantareas et al., 1988), while others argue that this lack of complexity in language may be detrimental to the child's ability to develop language (e.g., DePaulo and Bonvillian, 1978). In particular, the increase in maternal directiveness with children with developmental disabilities has been argued to negatively impact the interaction. Mothers of these children tend to exhibit more verbal and nonverbal behaviors that seek to control or direct the child's behaviors and actions (Marfo, 1990). Furthermore, correlational studies have found that mothers of infants with language impairments tend to spend less time engaged in conversational interaction, and tend to be less responsive compared to mothers of typically developing children (Alston and St James-Roberts, 2005; Hammer et al., 2001; Wulbert et al., 1975). Parents of children with ASDs who make more nondemanding comments that follow in to their child's focus of attention have children with better long-range language outcomes (Siller and Sigman, 2002). Similar to research on typically developing children, however, caregiver directives given when the caregiver and child share an attentional focus are associated with more positive child language outcomes in children with ASDs (Haebig et al., 2013a,b).

Importantly, many of these studies are correlational and child's behaviors likely influence the amount and quality of maternal language input at the same time that CDS impacts child language acquisition. For example, compared to typically developing children, children with ASD show a reduced preference for CDS over other stimuli (Klin, 1991; Kuhl et al., 2004; Paul et al., 2007), and attention to CDS is positively associated with concurrent language skills (Kuhl et al., 2004; Paul et al., 2007; Watson et al., 2010). Children with ASD also do not show the typical neural response to CDS as measured by EEG (Kuhl et al., 2004). These differences in child responsiveness to CDS may have a transactional impact on the quantity and quality of CDS that caregivers use with children with ASD that may in turn further restrict optimal language learning conditions for the children (e.g., Wan et al., 2013).

To address some of these issues, many interventions have focused on teaching parents how to become more responsive and facilitate mutual interactions. A recent meta-analysis found that parent-implemented language interventions, which often include a focus on increasing parent responsivity to their children, do have a positive impact on the expressive and receptive language skills of children with language impairments (Roberts and Kaiser, 2011).

Effects of Maternal Depression

Providing further support for the idea that CDS impacts language acquisition is the concomitant alteration in CDS and learning that occur related to maternal depression. Maternal depression has numerous effects on infant–mother interactions. The social interactions of depressed mothers tend to be reduced in quality, such that the less the mothers facilitate interactions, the less the children tend to be sociable, even with strangers (Stein et al., 1991). In terms of CDS, depressed mothers produce less exaggerated prosody and have delayed responses to infant vocalizations and more variable pauses (Bettes, 1988). These differences in speech behaviors have implications for infant learning, as infants of depressed mothers fail to learn that their mother's voice signals an upcoming face, although they are able to successfully learn this association from the CDS of unfamiliar nondepressed female speaker (Kaplan et al., 2002). However, infants of mothers with postpartum depression show less learning from the CDS of a nondepressed female speaker than infants of nondepressed mothers, and this difference continues even after the infants' mothers are no longer clinically depressed, suggesting exposure to early features of CDS may serve a 'social gating' function that supports the infants attention and responsiveness to others in relatively long-lasting ways (Kaplan et al., 2012)

Conclusions

The vast majority of the literature suggests that the adjustments in speech and nonverbal behaviors made by adults when interacting with children serve numerous purposes and provide benefits for young language learners. Not only have global relationships between maternal linguistic input and child language development been found, but research has also begun to elucidate specific features of CDS that support language learning. Furthermore, other aspects of communication beyond speech are also modified in child-directed interactions, including gestures and movements, which appear to benefit

language learning. Finally, evidence from developmental disabilities and maternal depression also support a strong role for CDS in language learning. Specifically, increasing maternal linguistic input with children with developmental disabilities can enhance language development, while the negative effects of maternal depression on CDS impairs language learning in children. In sum, there is increasing evidence that CDS is highly universal and beneficial for language acquisition.

Child Labor

Jackline Wahba, University of Southampton, Southampton, UK

Abstract

Child labor is still a cause of public concern. This article focuses on the relationship between poverty and child labor. Many children work to ensure the survival of their families and themselves. Furthermore, child labor today leads to poverty tomorrow: child labor perpetuates poverty and results in intergenerational poverty traps. Yet, policies banning child labor, even if they can be implemented, might harm the welfare of children and their families rather than help. This is why devising effective policies to address child labor is a challenging task and needs to tackle the root cause of the problem.

Child labor is still a cause of public concern in the twenty-first century. Recent estimates by the International Labor Office (ILO) indicate that there were about 168 million child laborers, aged 5–17 years, worldwide in 2012. Almost half of these children, around 85 million, work long hours under hazardous conditions. About 4 in 10 child laborers were younger than 12 years old (73 million). However, not all children work is seen as problematic, only when children employment interferes with the children's education and welfare that it is referred to as child labor. So, if child labor is a concern, what could be done about it?

Although this might seem to be a straightforward question, answering it is not so straightforward. In order to address the problem of child labor, it is necessary to understand the circumstances that lead children to work. Many economists believe that poverty is the main reason behind child labor. Many children work to ensure the survival of their families and themselves. However, child labor today, leads to poverty tomorrow. Child labor perpetuates poverty and results in intergenerational poverty traps. Yet, policies banning child labor, even if they can be implemented, might harm the welfare of children and their families rather than help. This is why devising effective policies to address child labor is a challenging task and cannot be done in isolation but has to tackle the root cause of the problem.

This article will examine the intricate relationship between poverty and child labor, and assess alternative policies to address child labor when children are driven to work by poverty. Section What Is Child Labor? will provide an overview of the linkage between poverty and child labor. Section Poverty Trap will examine the impact of child labor on poverty persistence, while Section What Are the Main Policy Implications? will evaluate the effectiveness of various policy recommendations to address child labor. Section Conclusion concludes.

What Is Child Labor?

Not all work done by children is classified as child labor. According to the ILO's Statistical Information and Monitoring Program on Child Labor (SIMPOC) 'child labor' is work that deprives children of their childhood, their potential and their dignity, and that is harmful to physical and mental development. Labor that jeopardizes the physical, mental or moral well-being of a child, either because of its nature or because of the conditions in which it is carried out, is known as 'hazardous work.' The ILO stipulates a minimum age for employment of 15 and 18 years for hazardous occupations and defines child labor by the ILO Minimum Age Convention, 1973 (No. 138) and the ILO Worst Forms of Child Labor Convention, 1999 (No. 182).

Estimating the number of child laborers is a difficult task. The ILO produced new child labor estimates for the year 2012 based on 60 datasets from national household surveys. The new global and regional estimates on child labor benefited from refinements embodied in the Resolution concerning Statistics of Child Labor, adopted by the 18th International Conference of Labor Statisticians (ICLS) in 2008. Based on those estimates for 5–17 years old in 2012, the incidence of child labor was 10.6% worldwide, and has fallen slightly from 14.2% in 2004. As **Table 1** shows, based on ILO (2013), that the largest number of child laborers was in Asia and the Pacific (77.7 million), but in relative terms Sub-Saharan Africa had by far the highest incidence rate around 21.4 versus 9.3% in Asia and the Pacific. One in 10 children was child laborer in Latin America and the Caribbean. The ILO estimates show that more boys than girls were engaged in child labor, in absolute and in relative terms.

The relative level of the child labor by economic activity can vary widely from one country to another. The ILO estimates suggest that child laborers were engaged in all the three broad groupings of economic activity (agriculture, industry, and services). However more than half (60%) were engaged in agriculture, 7% were employed in industry and 26% in services.

Table 1 Regional estimates of child labor in 2012, 5–17 years old

Region	*Total children (thousand)*	*Child labor (thousand)*	*Incidence rate (%)*
World	1585566	167956	10.6
Asia and the Pacific	835334	77723	9.3
Latin America and the Caribbean	142693	12505	8.8
Sub-Saharan Africa	275397	59031	21.4
Other regions	332143	18697	5.6

Source: ILO, 2013. Global Child Labor Trends 2008 to 2012, International Programme on the Elimination of Child Labor (IPEC). ILO, Geneva, p.10.

Two thirds (64 for boys vs 73% for girls) of child laborers were unpaid family workers making any form of intervention very difficult to implement. Paid employment and self-employment accounted respectively for 21 and 5% of all child laborers: only one in five child laborers were in paid employment. The overwhelming majority are unpaid family workers. The vast majority of child labor is found in rural settings and informal urban economy. Participation rates of children in economic activity are on average twice as high in rural communities than in urban centers. See ILO (2013).

Why Is Child Labor a Cause for Public Concern?

Child labor is a cause for concern, not only because of the number of children affected, which is still very high as seen above, but also and more importantly, because of the negative repercussions that starting working life too young has on the personal development of children. There is no disagreement that any type of child labor that involves abusive commercial exploitation of children or hazardous work is harmful and should be eliminated. Yet, when it comes to child labor in nonhazardous work the main concern is that child labor prevents children from receiving education. Low human capital base is the most serious developmental constraint in developing countries. Investments in child schooling add to the stock of human capital, and therefore to future income and living standards for society as a whole. Child labor constrains the children's abilities to benefit from education and schooling, thereby condemning them to perpetual poverty and low-wage employment.

Poverty and Child Labor

One of the most influential studies on child labor is the article by the Basu and Van (1998) that has spurred a large number of articles. The seminal theoretical article by Basu and Van (1998) argues that household decisions to send their children into employment are driven by poverty. Their model builds on two fundamental assumptions: first that households send children to work only if the adult wage is very low that the household subsistence requirements cannot be met without the income generated by the children- which they referred to as the luxury axiom. In addition, they assumed that adult labor and child labor are substitutes in production- known as the substitution axiom. They concluded that if a labor market is characterized by more than one equilibrium- one in which adult wages are low and children work, and another where adult wages are high and children do not work- banning child labor is a benign policy. But, in very poor countries, where there is only one labor market equilibrium at which adult wages are low, banning child labor can worsen the households' welfare.

This article has prompted a substantial body of literature and ignited the interest of many economists in child labor over the last decade aided by availability of large-scale, nationally representative household surveys from developing countries that has enabled more rigorous studies of this complex issue. Many believe that poverty is the main cause of child labor. However, the empirical evidence on the causal impact of poverty on child labor fails to consistently find a negative relationship between household income and child labor. For example, Ray (2000) fails to find positive relationship between child labor and poverty in Pakistan. As discussed by Edmonds (2008), there are two fundamental problems in studying the impact of poverty on child labor which are responsible for the lack of consistent relationship. First, poor households differ from rich households and those differences in many cases are due to reasons associated with child labor. Hence, disentangling these omitted factors from the underlying causal relationship is empirically difficult. Secondly, the relationship between household income and child labor is a two-way one where household income affects child labor but child labor affects household income as well. Thus the second challenge is to control for the endogeneity between household income and child labor.

Studies that use panel data and track children in the same household over time consistently find that large increases in child labor are associated with substantive declines in household incomes. For example, Beegle et al. (2006) track children over a 3-year period in rural Tanzania and find that children tend to work when households experience unexpectedly poor harvest, and that children stop working when households recover from the bad harvest. Also, Duryea et al. (2007) find that child labor increases during adult unemployment spells in urban Brazil. Edmonds (2005) using a panel dataset of Vietnamese households from 1993 to 1997 finds that improvements in per capita expenditure explain 80% of the decline in child labor.

Some studies have taken a different approach by focusing on market wages as opposed to parents' wages or income. As discussed above, Basu and Van (1998) stress the role of adult market wage; they assume that households send children to work only if the adult market wage is very low and as the wage rise they withdraw their children from the labor force. Thus, the elasticity of child labor supply to adult market wages is important in particular for policy formulation. Wahba (2006) finds support for this hypothesis, examining the relationship between adult market wages and child labor in Egypt and finds that a 10% increase in the illiterate male market wage lowers the probability that a child engages in wage work by 22 for boys and 13% for girls.

Another contentious issue in the empirical evidence on the relationship between household income and child labor is what Bhalotra and Heady (2003) refer to as the wealth paradox where they find a positive correlation between market work participation and household assets. Since land is usually strongly correlated with a household's income, this seems to challenge the presumption that child labor involves the poorest households. Basu et al. (2010) argue that the missing ingredient may be an explicit modeling of the labor market. They develop a simple model which suggests the possibility of an inverted-U relationship between land holdings and child labor. Using a unique data set from India, that has child labor-hours they find that, controlling for child, household and village characteristics, the turning point beyond which more land leads to a decline in child labor occurs around 4 acre of land per household. Thus taking into account the nonlinear relationship between household's income and child labor explains this wealth paradox.

Households also may send children to work not only in order to augment household income but also to manage better the income risk they face. Child labor can be part of a strategy to minimize the risk of interruption of a household's income stream and hence to reduce the potential impact of job loss by a family member or of failed harvest for example. More importantly, because of capital market imperfection in developing countries, poor households cannot borrow to manage during the bad times and in many cases they have to rely on their children's earnings for survival, see e.g., Baland and Robinson (2000). For example, Dehejia and Gatti (2005) find a negative relationship between child labor and access to credit, where access to credit is proxied by the extent of financial development.

Meanwhile at the macrolevel, there is a debate on whether international trade and globalization reduces or increases child labor. A common argument in the child labor literature is that foreign trade, and globalization in general, increases child labor by increasing the demand for goods produced by children. See Edmonds (2008) for an extensive summary of this literature. For instance, Edmonds and Pavcnik (2007) study the relationship between trade liberalization (measured as the change in the relative price of an exported commodity) and child labor using household level data from Vietnam. They find that higher rice prices are associated with declines in child labor, suggesting that in this case greater market integration is associated with less child labor, not more. Fafchamps and Wahba (2006) show that children living in or around cities work more for the market in the form of wage work or small business employment. The increased intensity of market exchange associated with cities thus appears to be empirically correlated with an increased involvement of children in market-related forms of work. At the same time, work by children on the family farm and on household chores falls dramatically with proximity to urban centers. These results suggest that urban proximity in Nepal is associated with an improvement in child welfare – at least as far as total child labor and education are concerned.

There are potentially many other determinants for child labor besides poverty. One strand of the child labor literature focuses on the lack of availability of good schools. The overall condition of the education system can be a powerful influence on the supply of labor. The failure of the education system may lead many parents to view work as the preferred option for their children because education is no longer a road toward obtaining a degree and a civil service job. In addition, traditional factors such as rigid cultural and social roles further limit educational attainment and increase child labor. Another strand of the literature pushes sociodemographics, family characteristics and social norms as important determinants of child labor. Parents' education play an important role: educated parents are less likely to send their children to work. The child's age, gender, and birth order also affect child labor. Furthermore, cultural factors matter, so there is a huge variation among patterns and incidence of child labor in different countries that stem from cultural and social norms and traditions.

Are Poor Households Acting Rationally?

One might ask, are poor households acting rationally by sending their children out to work? Well, to be able to answer that question, let's consider a very simple model of household time allocation. Let's assume that a child can allocate his/her time between three activities: schooling, work, and leisure. The family allocates the time of its children to wherever the perceived private return is highest. The decision by any family to send his or her child to school or to work depends on the private benefits and costs. First, let's consider the private returns and costs of schooling. The benefits obtained from education clearly depend on the quality of the education the child is likely to receive and how that education is likely to increase the child's productivity in the future and therefore his/her future earnings. The overall condition of the education system can be a powerful influence on the supply of labor. Low quality of the education, for example too crowded classes or bad teaching, would reduce the benefits of schooling. As a result, parents may find no use in sending their children to school when they could be home learning a skill (for example, agriculture) and supplementing the family income. Schooling is costly even if it is free (no fees) because there are other direct costs involved, such as books, uniform, and travel. Also, there are indirect costs of schooling; the opportunity cost of child schooling (the loss incurred by a family whose child is in school rather than working) is wage rate earned in the labor market by that child. The higher the opportunity cost of school attendance in relation to a household's income, the greater the perceived need for the child to work. Schooling problems, such as schools being too far away, would also increase the cost of education and make it unattractive for parents to invest in children schooling.

Families which send their children to school give up short term consumption in favor of investment in human capital of the child, which is likely to pay off in old age. Families which choose to engage their children in paid market work, sacrifice the future of their children, and hence that of their own, in an attempt to raise their current standard of living of the household. Families' decisions to take a child out of school and send him or her to work is typically a rational decision based on a comparison of the discounted future stream of benefits accruing to the child, and/or household from the child's education relative to the opportunity cost of the child's time which is his/her productivity at work, plus the direct costs of education. Poor households are likely to be present-oriented as compared with more well-off households and would be likely to discount the future more than well-off households and are therefore more likely to take their children out of school.

Poverty Trap

The main concern about child labor is its detrimental effects on schooling. Few studies have examined the dynamics of child labor. For example, Basu (1999) show that child labor, when is undertaken at the expense of human capital formation, would lead to child labor trap: if children work, they will not go to school and will have low human capital. As adults, they will also need to send their children to work thereby perpetuating child labor in the future. Households that are very poor are much more likely to send their children to work, and child labor contributes to poverty in the next generation by reducing schooling attainment. For example, Ray (2003) finds that an additional hour of wage work in Ghana is associated with more

than a year's less completed educational attainment. This circular pattern of positive feedback between poverty and child labor may lead to a vicious cycle of poverty, in which the descendants of the poor remain poor because they were poorly educated. This cycle can be the foundation of a classical 'poverty trap.'

There is little empirical evidence on the intergenerational transmission of poverty in developing countries, in particular, on how child labor perpetuates poverty from one generation to another, or on how parents who were child laborers are more likely to have their children work as well. Parents who worked as children are more likely to have underinvested in schooling and become poverty-trapped and hence would expect their children to work as well. The relationship between family background, such as race, ethnic origin, religion and in particular education, and child labor is fairly established in the empirical literature. Studies show that a low level of parents' educational attainment is an important factor in increasing the likelihood of children working.

A few studies have examined the effects of child labor on the children once they become adults. Ilhai et al. (2000) examine the effects of child labor on lifetime earnings and poverty status using retrospective data on adult earnings and information on whether adults worked as children in Brazil. They find that entry in the workforce before age 13 results in a reduction in adult wages of 13–17% and an increase in the probability of being in the lowest two income quintiles of 7–8%. They estimate the effect of child labor both independent of its effect on education and through its effects on education. They find both effects to be significant. They argue that early entry in the labor force reduces years of education and lowers the returns per year of schooling. Similarly, Emerson and Souza (2003) explore the evidence of intergenerational persistence of child labor. They build an overlapping generation model of the household child labor decision to capture a child labor-trap story and then examine the empirical evidence using household survey data from Brazil. They find that adults who worked as children have lower earnings even when controlling for their educational levels and that the likelihood of being child laborer increases the younger the parents entered the labor market. They explain the persistence of child labor above that of parental education and household income, given their theoretical model, to be the result of some unobservable human capital characteristic i.e., human capital accumulation is not determined only by the amount of education but also by maybe the quality of education, the level of education of siblings or the household environment. Wahba (2006) also provides direct evidence on the intergenerational persistence of child labor where she finds that parents who themselves worked as child laborers are more likely to send their children to work in Egypt.

Thus child labor if driven by severe poverty is highly likely to reinforce itself and result in an awful equilibrium of persistent poverty, excessive child labor and low education over generations.

What Are the Main Policy Implications?

Tackling child labor is not straightforward. Various policy options such as banning child labor or trade sanctions, even if they can be implemented, are unlikely to be effective in eradicating child labor. Indeed such policies may even be counterproductive because they would harm the same people they want to protect namely, the poor. Basu and Zarghamee (2009) argue that boycott and trade sanctions may increase child labor. Their argument is that sanctions tend to depress child wages, and that the response of poor families depending on child labor to avert extreme poverty may be characterized by strong income deficits. Doepke and Zilibotti (2009) use a political-economy perspective to show that these types of international action on child-labor tend to lower domestic political support within developing countries for banning child-labor. Hence, international labor standards and product boycotts may delay the ultimate eradication of child-labor.

An alternative policy option that is often advocated to address child labor is drawing children into school. To the extent that schooling displaces child labor, policies that affect the costs of or the returns to school might prove effective in reducing child labor. However, Ravallion and Wodon's (2000) point that increased school enrollment does not necessarily lead to an equal fall in child labor as they find that Bangladesh's Food for Education program increased school attendance, but reduced the incidence of child labor by only a small proportion. Kondylis and Manacorda (2012) go one step further, by arguing that increases in enrollment induced by improved school accessibility might, as an unwanted consequence, lead to a rise in child labor. Similarly de Hoop and Rosati (2012) investigate the impact of school subsidies and increased access to education on child work using data from 'Burkinabé Response to Improve Girls' Chances to Succeed' (BRIGHT), an integrated program that aims to improve school participation in rural communities in Burkina Faso. They find that BRIGHT substantially improved school participation, yet it did not reduce – in fact may have increased – children's participation in economic activities and household chores. They argue that if education programs are implemented to achieve a combination of increased school participation and a reduction in child work they may either have to be combined with different interventions that effectively reduce child work or they may have to be tuned more carefully to the incentives and constraints the child laborer faces.

A number of countries have adopted policies designed to discourage child labor and increase schooling through conditioning cash transfers to poor households on children attending school. The PROGRESA program is particularly important as one of the first conditional cash transfers that incentivized families to send their children to school. The cash transfer increases with the age of the child in order to compensate the household for the older child's greater opportunity cost of schooling. In addition, at secondary school ages, girls receive larger cash payments for attending school than do boys. Several studies find the program to have had a significant reduction in child labor e.g., Schultz (2004) and Skoufias and Parker (2001).

A recent study by Edmonds and Schady (2012) considers how child time allocation in Ecuador responds to receipt of the *Bono de Desarrollo Humano* (BDH) cash transfer. The BDH cash transfer is randomly assigned to some eligible poor households and not to others. The BDH transfer is $15 per household per month, 7% of monthly expenditures for recipient households,

and does not vary across eligible families. The transfer is paid to mothers, and does not have any conditions attached. They find that $15 a month given as the BDH reduces child labor. These results are consistent with a growing literature that documents that cash and in-kind transfers can reduce child work. Their findings highlight the central role that poverty plays in the child labor decision, and suggest the possibility of affecting large changes in child labor with relatively modest investments in poverty relief.

Conclusion

Parents do not send their children into paid employment out of a selfish preference. In the vast majority of cases, children are driven into work by poverty and the inability of poor households to manage external shocks. Households that are very poor are much more likely to send their children to work, resulting in the poverty of their children when they become adults. Hence child labor leads to a vicious cycle of poverty. Yet, any measures aiming to ban child labor might hurt poor children by reducing their welfare.

As a result addressing child labor needs to be mindful of its main driver and deal with the root of the problem: poverty. Cash Transfer programs have proved success in mitigating the poverty effects that drive children out of school and into labor markets. For example, in Brazil, the 'Bolsa Familia programme,' which provides cash transfers to some 820 000 children aged 7–14, is estimated to have increased school attendance by 4% nationally, but 9 and 12% respectively in rural regions and the north-east (the poorest part of the country). There is now a growing body of evidence that both conditional and unconditional cash transfers, in the range 0.5 to 2% of GDP, can play a role in increasing child schooling and reducing child labor.

Any intervention to control child labor should recognize the powerful market forces that give rise to child labor in the first place as there are many pitfalls and risks of backlash that occur in this area of complex interaction between household economics and market structures. As long as the main cause that pushes children to work, namely poverty, is not tackled, child labor will never be a phenomenon of the past. However, the recent evidence on the success of cash transfers in reducing child labor and poverty is promising.

Child Neglect

Beth Casey, Durham University, Durham, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In recent years there have been important academic and theoretical developments around child neglect, including the nature of the phenomenon, causes and consequences, and the professional approaches most appropriate in neglect cases. This article begins with an analysis of how awareness of neglect has grown, before examining the complexity of definitional issues. It goes on to explore the ways in which knowledge in relation to neglect has been constructed, examining the major constructions and contextual issues that have emerged. Key contextual factors including the relationship between neglect and poverty and the gendered nature of neglect and policy responses are discussed.

Introduction

Child neglect has become an increasingly important issue in recent years with academic and theoretical developments, covering the nature of the phenomenon, causes and consequences, and the professional responses in neglect cases. This article begins with a discussion of the 'neglect of neglect' and then analyzes how awareness of neglect has grown, before examining the complexity of definitional issues. It then explores how knowledge in relation to neglect has been constructed, examining the major constructions and contextual issues that have emerged. Key contextual factors, including the relationship between neglect and poverty and gendered nature of neglect and policy responses are discussed.

The Neglect and Reemergence of Neglect

The 'neglect of neglect' in the child maltreatment field has been noted by researchers over a significant period (Dubowitz, 2007; Gabarino and Collins, 1999) with Coohey (1995: p. 885) concluding that "the overwhelming focus of research and theory building has been on sexual abuse, physical abuse or child maltreatment." Stone (1998) suggests that neglect is poorly understood by practitioners theoretically and that training for practitioners in this area is lacking. The reasons underlying the failure of some parents to provide adequate care for children remain significantly underresearched (Hildyard and Wolfe, 2007).

Coupled with these gaps in research and theory is a growing awareness since the 1970s about the extent to which class-based assumptions can influence practice, leading, according to Scourfield (2003: p. 109), to "a reluctance to bring families into the child protection system" on grounds of being "poor, shabby and dirty." Stone (1998: p. 88) suggests that the relatively low profile of neglect might be "due to the fact that neglect is a long-term developmental issue rather than a crisis." Further, physical abuse may be more tangible and visible, commanding more attention from professionals than neglect, which is viewed as an act of omission (Garbarino and Collins, 1999).

Several studies have highlighted the 'neglect of neglect' at a practice level. Stone (1998) found that neglect cases would be given low priority and were filtered out of the system at various thresholds until a specific incident of sexual or physical abuse arose in the same case. Similarly, Swift (1995: p. 78) suggests that "because neglect is usually characterized as being of long duration, such a case may easily slip to the bottom of a worker's list of action priorities until a child is clearly put at risk."

The 'neglect of neglect' is increasingly being challenged through recognition of its increased incidence and evidence of its adverse effects on children. Neglect has become the largest category of child protection registration in the UK (Scourfield, 2003; Turney, 2000) and accounts for the highest percentage of maltreatment in the US and Canada (Sedlak et al., 2010; Ruiz-Casares et al., 2012). In the Swedish context, Kaunitz et al.'s study revealed that for children aged 0–12, 62% of referrals concerned neglect (Cocozza and Hort, 2011).

Research evidence strongly supports the view that child neglect can lead to poor outcomes for children in both the short term and long term (Daniel and Taylor, 2006). Neglect can impact upon the child's emotional, physical and cognitive, psychological and behavioral development (Glaser and Prior, 2002). Deleterious effects include anxiety and low self-esteem, problematic behavior, educational underachievement, and adverse impacts upon peer and social relationships (Glaser and Prior, 2002). The long-term impact on children may be influenced by the severity, chronicity, and developmental stage at which the neglect occurs (Hildyard and Wolfe, 2002).

Defining Neglect

Definitions of neglect are varied and contested, making investigation of professional responses to neglect complex. Daniel et al. (2011: p. 13) argue that neglect can be defined both broadly and narrowly, highlighting a distinction between "neglect as a concept denoting the experience of a child whose developmental needs are not being met and 'neglect' as an operational, legislative or policy label." Hence, definitions vary depending on purpose, for example, criminal proceedings, determining eligibility for services, and investigating allegations and research (Daniel et al., 2011). When defining neglect then as a "category for compulsory action," definitions tend to be narrower (Daniel et al., 2011: p. 15). In

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28011-2

the UK, national guidance in the shape of *Working Together* defines neglect as:

> the persistent failure to meet a child's basic physical and/or psychological needs, likely to result in the serious impairment of the child's health or development.
> (HM Government, 2013)

In the UK, legally neglect is embedded within The Children Act's (1989: section 31) definition of significant harm: "the child is suffering, or is likely to suffer significant harm; and that the harm or likelihood of harm is attributable to a lack of adequate parental care or control." Common to most definitions of neglect is the notion of parental omission of care, failure to provide for (Garbarino and Collins, 1999; Swift, 1995) or protect the child (CIS, 2008). Most definitions address the failure to meet a child's basic needs (Garbarino and Collins, 1999). In Australia there is no uniform legal definition of neglect, although eight aspects of neglect are covered in different states and territories (Lawrence and Irving, 2004). In other countries, for example, China, there has been no attempt to develop a legal definition of maltreatment (Liao et al., 2011).

In the UK, applying the *Working Together* definition of neglect in practice becomes problematic, particularly given a lack of guidance on the application of the broad statement and explanation of key terms (Turney, 2000). Legally informed definitions assert a dichotomous categorization of neglect, in which the child is not neglected (Polansky et al., 1981). Although the legal definition of neglect appears 'concrete' (Daniel et al., 2011), in practice it is recognized that neglect is a "complex and multifaceted phenomenon" (Stone, 1998: p. 90) and "notoriously difficult to define" (Turney, 2000: p. 249). Moreover, in China, where no legal definition exists there is no consensus among Chinese researchers regarding how neglect should be defined and conceptualized (Liao et al., 2011).

Critiques of narrow definitions of neglect have highlighted the focus on parental omission rather than on children's unmet needs (Dubowitz et al., 1993; 2007). Dubowitz et al. (1993) argue that legal definitions of neglect tend to be narrow and carry the implicit assumption of parental responsibility, while failing to recognize the complexity of the phenomenon. They argue that the focus of concern should 'be on children and their unmet needs, rather than on the presence or absence of parental (or caregiver) behaviors.' Narrow definitions may fail to take into account the dynamic nature of children's age and developmental levels, which influences the level and type of care they require (Zuravin, 2001). Crucially, by defining neglect more broadly, Dubowitz et al. (1993) argue that neglect should be conceptualized within an ecological framework, recognizing the wider social context in which children are neglected. At policy level in the UK, the *Framework for the Assessment in Need and their Families* (DoH, 2000) promoted a broader understanding of neglect taking an ecological approach that positions the child within the family, wider community, and social factors. Although in England the government's revised statutory guidance *Working Together* (HM Government, 2013) has superseded that which originally accompanied the Assessment Framework in 2000, the model itself is retained in the new guidance. A systems approach allows the practitioner to understand the interplay of biological, psychological, social, and cultural factors in child neglect. Further, it is child centered and rooted in child development specifically through the incorporation of the dimension of the 'child's developmental needs.' In countries with a 'family service' model, including Denmark, Finland, Sweden, and Norway (Skivenes, 2011), child maltreatment is understood in terms of the wider context and circumstances in which a child is cared for including psychological, familial, and socioeconomic problems (Cocozza and Hort, 2011).

Neglect can be defined variously in terms of parental characteristics or behavior or the impact of both of these factors upon the child (Daniel et al., 2011). Parental care, and lack of it, clearly exists on a continuum, ranging from excellent to grossly inadequate (Dubowitz, 2007). Given that neglect exists on a continuum, Dubowitz (2007: p. 604) suggests that it is difficult to identify when "exactly the inadequacy of care becomes problematic" with practitioners relying on measures such as 'faltering growth' or the notion of developmental milestones.

Research highlights the heterogeneity of neglect as a phenomenon. For example, Zuravin (2001) identifies several subtypes of neglect with different operational definitions. Determining neglect "rests on an assessment of frequency of the omission as well as the likelihood and severity of harm" (Dubowitz et al., 1993: p. 18). Some omissions in care are not likely to be harmful unless they are more frequent (Dubowitz et al., 1993). Zuravin (2001: p. 50) suggests that certain types of neglect require chronicity, for example, in discussing educational neglect she suggests that "a child must be absent from school for a minimum of twenty days without legitimate reason". A further complexity concerns whether definitions should include intentionality, whether neglect is the result of a desire to harm, of 'ignorance' or of circumstances such as poverty (Zuravin, 2001). Liao et al. (2011: p. 1710) suggest that in Chinese culture neglect is understood as being "unintentional and is generally attributed to ignorance." A broader definition of neglect widens the responsibility from parental blame to include wider social and institutional responsibility.

From this brief review of the existing literature on defining neglect, it is evident that wide-ranging categorical and conceptual differences exist within and between definitions. Such differences are likely to both reflect and influence how neglect is dealt with by social workers in practice and the way in which service users understand the basis of professional involvement in their lives.

Constructing Child Neglect

Several authors, mainly within the UK and US, have explored the constructions and discourses given precedence within social work practice relating to neglect.

A Preoccupation with Dirt and Disorder

In his study of child neglect responses in a social work team, Scourfield (2003) found that professional discourses drew upon selected messages from research. He cites the influence of findings from the *Bridge Child Care Consultancy* (1995) and *Child Protection: Messages from the Research* (DoH, 1995). The former emphasizes physical neglect and the servicing of the

child's body, "their neglected child is dirty and smelly" (Scourfield, 2003: p. 111), while the latter highlights the emotional impact of parenting styles characterized as "low warmth, high criticism" (DoH, 1995: p 19). Interestingly, the practical construction of neglect was "more influenced by the discourse of the servicing of the child's body" (Scourfield, 2003: p. 112). Swift (1995) found that physical neglect predominated both in relation to casework records and in social workers' talk about neglect. Similarly, in considering factors of concern in a chronic case scenario, Horwath (2007) found that 135 professionals focused on lack of supervision and physical harm with only six considering lack of stimulation and nine poor nurturing.

Swift (1995) and Scourfield (2003) indicate that there exists a professional preoccupation with dirt and disorder, both in relation to the child's appearance and home conditions. In Scourfield's (2003) study deciding whether a home was tidy and clean was "judged against tacit standards," involving levels of order and cleanliness (Scourfield, 2003: p. 113). Additionally, adequate feeding was "another abiding concern about the servicing of children's bodies" (Scourfield, 2003: p. 116). The emphasis in practice on physical neglect is noteworthy, given that there is also some evidence that professionals recognize the damaging effects of emotional neglect. For example, Horwath (2007) found that 75% of respondents agreed that a high criticism, low-warmth environment is damaging for a child.

Measuring and Proving Neglect

The dominant focus on physical neglect in practice may be explained through its being observable and visible: "you can see and smell dirt, check a child's weight" (Scourfield, 2003: p. 126). In contrast, emotional neglect is considered less easy to evidence, viewed as less tangible, more subjective, not as visible, and more difficult to observe developmental delays (Casey, 2013). Several studies have indicated that physical neglect dominates as it is easier to prove in court and in legal terms. The visibility of physical neglect is well placed in a legal context embedded in objectivity, 'facts,' and rational evidence (Casey, 2013). At the same time, "harm to children through neglect is difficult to establish in legal terms because it is incremental, often invisible and not directly observable as an outcome of parental behaviour" (Swift, 1995: p. 84). In a context in which professionals are under considerable pressure to 'get it right,' it is not surprising that "dirty, hungry, ill-clad children are bodies of evidence…concrete proof of parental failure to clean, feed and clothe" (Scourfield, 2003: p. 123). Moreover, this focus on physical needs is embedded within a climate preoccupied with risk (Scourfield, 2003) and "may reflect the incident driven system which has dominated child welfare practice for over twenty years" (Horwath, 2007: p. 1291). This focus on physical neglect and needs marginalizes the child's other needs (Horwath, 2007) and presents a partial view of children's welfare (Scourfield, 2003).

'Good Enough' and 'Bad Enough' Parenting

Given the complexities of defining neglect, the point at which care becomes inadequate is difficult to ascertain. In Rodriguez's (2002) study, investigating abuse-reporting decisions of professionals on abuse scenarios, accuracy was lowest for child neglect. Identifying neglect involves professional judgment of whether parenting is of an adequate standard (Lawrence and Irving, 2004). In Horwath's study, 25% of professionals believed staff in social work departments accept lower standards of parenting than other professionals (Horwath, 2007). Alongside differences between professional groups, the notion of 'good enough' parenting is also contested between social workers. In the Finnish context, the criteria for child maltreatment, varies between areas, teams, and officers as a result of "different organizational cultures, communities and…norms and expectations about appropriate childhood and parenthood" (Pösö, 2011: p. 116). In Casey's (2013) study, standards were viewed as dependent on experience, with newly qualified workers adopting higher standards of care to warrant action. Accepting lower standards of parenting may result when social workers work to the rule of optimism (Daniel, 2000). While social workers may accept relatively low standards of care, thresholds into services may be high. In this context, professionals make decisions as to whether care is bad enough to warrant services. Very high thresholds can cause cases to be closed or deregistered from child protection services too rapidly, resulting in situations of repeated registration, deregistration, and reregistration (Casey, 2013). Defining neglect becomes part of service rationing strategies, with levels of 'good enough' care determined by available resources (Casey, 2013).

Contextual Factors

Gender and Neglect

Mothers are "overwhelmingly identified as perpetrators of neglect" (Daniel and Taylor, 2001: p. 24). The question of responsibility for the maltreatment of children is "a key gender controversy" (Scourfield, 2003: p. 23) and studies have identified that gendered constructions of women are mainstream organizing principles (Scourfield, 2003). As Turney (2000: p. 50) argues, care and nurturing are identified with the feminine, in the West: "the association between caring and mothering…has particular salience for a consideration of child neglect."

Social workers' holding of women responsible (Strega et al., 2008) in cases of neglect builds on and reproduces traditional psychoanalytical positions and attachment theory, which are explored below, specifically around the 'good enough' mother. This association between femininity and caring has implications for understanding neglect with any breakdown in care being attributed to women (Daniel and Taylor, 2006). As Daniel and Taylor (2006: p. 427) elaborate, the theoretical underpinning of the majority of research on neglect is that: "neglect is an indication of a lack of nurturing; nurturing is carried out by mothers; therefore, when nurturing is absent the problem must be a problem of mothering."

Research and theory on child neglect is influenced by the assumption of women as primary caregivers (Daniel and Taylor, 2006). When fathers are included, research "tends to focus on the father's relationship with the mother and his presence or absence in the home" (Daniel and Taylor, 2006: p. 428). In Gaudin et al. (1996) study, fathers had limited involvement in child rearing and supporting the mother.

The mother then becomes a key variable in writing about child neglect, in terms of role rejection, lack of nurturing, knowledge, immaturity, and poor nurturing (Swift, 1995). Swift (1995: p. 89) suggests that "many researchers are concerned with establishing the main causal variables of neglect, they also contribute to the definition of the problem by framing it in personal and intra-familial terms."

Characteristics of Poor Parenting

A range of studies have investigated the characteristics of neglectful parents, with the focus mainly on mothers' personalities, caring roles, attitudes, relationships, and attachment histories (Coohey, 1995; Hildyard and Wolfe, 2007; Polansky et al., 1981). Egeland and colleagues' longitudinal study of Minnesotan mother–child interaction among first-time mothers considered to be at risk of maltreatment concluded that, for children aged six, "psychologically unavailable mothers were more tense, angry, depressed and confused" and less intelligent (MacDonald, 2001: p. 50). Similarly, Hildyard and Wolfe's (2007: pp. 898–899) comparative study of neglectful and nonneglectful mothers' responses to child emotions and behaviors found that "neglectful mothers had significantly more children; had experienced a greater degree and severity of maltreatment in their own childhoods; were more likely to be unemployed…and reported significantly more depressive symptomatology than the comparison sample."

Connell-Carrick and Scannapieco (2006) found that neglectful caregivers were characterized by a history of depression and attempted suicides. Substance abuse, mental illness, or learning difficulties were common in case files in Stone's (1998: p. 92) study that concluded that "most caregivers were significantly damaged individuals who were ill-equipped, emotionally or practically, to care for children." In Casey's (2013) study there was a preoccupation with the balance between child and parental 'needs' within case files and professional dialog: neglectful mothers were considered a risk when they put their own needs first. Gaudin et al. (1996: p. 367) examined casework assessments and found that neglectful families were viewed as "less healthy; less able to resolve conflicts; less cohesive…less well led and less verbally expressive." Similarly, Connell-Carrick and Scannapieco (2006) indicate that neglectful parents have fewer parenting skills, including effective communication and coping with stress. They were also viewed as lacking empathy and expressing dislike toward their child.

Crittenden (1999) identifies three 'types' of neglect within which the characteristics of parents are seen to differ:

- *Disorganized neglect*: families are characterized as multi-problem, disorganized, and crisis prone. Parents are described as failing to attend to children's needs of all kinds until crisis point;
- *Emotional neglect*: parents may provide materially for their children but do not give adequate attention to their emotional needs; and
- *Depressed neglect*: parents are withdrawn and do not perceive their children's needs. Children become silent and depressed.

Drug and Alcohol Misuse and Other 'Risk' Factors

Studies have also focused on specific risk factors for child neglect, including alcohol and substance misuse, mental health issues, learning disability, and domestic violence. Cleaver et al. (2007) highlight considerable evidence showing that children who grow up in families where there is domestic violence and/or parental alcohol or drug misuse are at increased risk of significant harm. Further, Forrester (2000: p. 241) found that "substance-using families were very significantly over-represented in neglect cases" with 9 out of 10 children whose parents used heroin registered as neglected. Alcohol misuse was also cited in 20 out of the 59 children registered for neglect. Similarly, Christoffersen and Soothill (2003) found that a mother's alcohol abuse contributed significantly to children's neglect. Cleaver et al. (2007) found that in social work case files, three-quarters of children living with domestic violence and/or substance misuse had unmet needs in at least one area of development. Cleaver et al. (2007) also revealed how many families experienced a combination of domestic violence, parental alcohol misuse, drug misuse, mental illness, and learning disability.

Research indicates that fathers may exacerbate the likelihood of neglect, e.g., if they are using household income to finance substance misuse. Scourfield (2000: pp. 376–377) argues that "the abusive man has a complementary relationship to the neglectful woman where his violence, abuse of money, avoidance of domestic work and frequent absence from the home are seen to hinder her care of the children." In Casey's (2013) discussion of the professional construction of 'responsible neglectful mother/dangerous or absent men', women were held responsible for being unable to meet the child's needs as a consequence of the emotional impact of men's violence.

Family 'Dysfunction'

Coohey (1995: p. 885) argues that "neglectful mothers exchange fewer resources with both their partners and mothers." Stone (1998) found that 7 out of 20 neglectful families lived in reconstituted families: mostly a mother plus a new partner. Relationships and family dysfunction were central concepts guiding practitioners' understandings of how children became neglected (Stone, 1998). Gaudin et al. (1996) compared family functioning in nonneglectful and neglectful families and found that neglectful mothers had more unresolved family conflict than those in the comparison group. Neglectful families also rated themselves as having "less closeness and less clear internal family boundaries; poorer negotiating skills; …less responsiveness to other family members' statements; less warmth…and less empathy toward one another" (Gaudin et al., 1996: pp. 368–369). Coohey (1995: p. 885) found that neglectful mothers "were more likely to state their mothers had fewer positive attributes…their relationship was less positive and they were less interested in receiving resources from their mothers." Significantly, explicit discussion of fathers is absent from many studies of neglectful families and, where they are included, are addressed primarily regarding their relationship with the mother (Daniel and Taylor, 2006) and being a resource for the mother's caring

role. Casey (2013) found that within professional constructions, mothers were blamed for the impermanency, chaotic, and 'inappropriate' nature of their relationships with men contributing to or exacerbating neglect.

Intergenerational Neglect

The intergenerational nature of neglect and abuse has been a consistently reported, but somewhat controversial finding of child maltreatment research (Connell-Carrick and Scannapieco, 2006; MacDonald, 2001). Stone (1998: p. 92) found repeated references in case file data of mothers' own experiences of neglect and abuse: "mum has never experienced effective nurturing parenting herself." In this study, 18 out of 20 cases scored positively for poor parenting of caregivers, with many having a history of neglect or abuse and experiences of the care system. Moreover, Hildyard and Wolfe (2007) found that mothers with an unresolved attachment status had the most severe difficulties in interpreting their own child's emotions. Hildyard and Wolfe (2007: p. 904) argue that research has indicated that experiences of childhood maltreatment, produces "negative representational models…based on…self-blame and shame," adversely affecting caregiving abilities.

Theories about the intergeneration transmission of child maltreatment are highly gendered, with the overriding focus on the mother–daughter relationship. For example, Coohey states (1995: p. 893) that "the mechanisms that perpetuated child neglect may lie in personality and behavioural traits of the mother…that are then reproduced in the adult daughter through the mother-daughter relationship."

Attachment Theory and Mother-Blaming

Swift (1995) suggests that 'bonding theories' are highly influential within social work practice in cases of neglect, and establish the *mother* as primarily responsible for meeting both material and emotional needs of their children. An implicit conceptualization of the 'good enough' mother is central to all of these theories. Although an understanding of attachment theory is considered crucial in identifying neglect, attachment theories have been critiqued for upholding mothers as solely and individually responsible for inadequate care and for blaming and pathologizing women.

Furthermore, physical descriptions of mothers "directs us to see poor care as closely connected to 'defects' in the mother and simultaneously directs attention away from the experienced problems of the mother" (Swift, 1995: p. 110). Although, as Swift (1995: p. 89) suggests Polansky's influential studies deemed poverty and social deprivation as important factors when investigating neglect, the personality features of mothers were seen as the overriding and primary cause.

Specifically, the 'cycle of neglect' discourse "render[s] the social and economic context not only invisible but irrelevant" (Swift, 1995: p. 113). The neglect schema, argues Swift (1995: p. 99), validates preexisting individualized services, which are 'directed at changing people rather than addressing social ills': services that provide 'reparenting' to break the cycle. Hence, mothers are policed to care, to reach a state where she is less needy, a state, which she needs to arrive at herself in the face of limited resources (Swift, 1995). Such blaming ignores the reality of women's lives, including material factors of limited financial resources or housing (Kufeldt et al., 2003).

Poverty and Neglect

Swift (1995) identifies two main historical discourses about the attribution of cause surrounding child neglect: personality and poverty. The relationship between poverty and child neglect is now commonly recognized. Slack et al. (2004) highlight an inverse relationship between income levels and child neglect. Similarly, Stone (1998: p. 93) highlights that "neglected children evidently suffer from poverty both in their material and their emotional environments." Professionals in Casey's (2013) study recognized that living in poverty can adversely impact the 'ability to parent' and increase the risk of neglect, while being aware of the danger in assuming that poverty was the sole cause or factor in cases of child neglect.

Beyond Simple Causation

Despite the above findings, there has, however, been a move away from notions of poverty as a simplistic *causal* factor of child neglect, toward an acknowledgment of the complex *relationship* and correlations between the two (Dubowitz et al., 1993; Slack et al., 2004). Turney (2000: p. 54) argues that practitioners need to consider the "importance of intrapersonal dynamics but…also highlight the nature of relationships between individuals, their families and wider communities." Garbarino and Collins (1999) emphasize the interplay of biological, psychological, social, and cultural factors.

At the same time, there is evidence that high unemployment and poverty hinder parental ability to provide care, increasing the likelihood of neglect. Garbarino and Collins (1999) suggest that neglect is a function of influences on caregivers that lead to lowered morale, deteriorated functioning, and depression. Cleaver et al. (2007) have highlighted that domestic violence and parental substance misuse can impact on housing, income, and social integration. Studies have indicated that parents' personal issues interact with contributory factors including poor housing, an absence of reliable child care, inadequate income, and institutional constraints (Casey, 2013; Dubowitz et al., 1993; Garbarino and Collins, 1999).

Connell-Carrick and Scannapieco (2006) found that families who were rated as having a poorer social climate (including social support and isolation) were more likely to be substantiated for neglect. Dubowitz et al. (1993: p. 9) argue that "the interactions between children and parents are influenced by community and societal factors such as the availability of child care and poverty." Swift (1995) argues that living in poverty impedes parents' capacity to improve their parenting through an absence of access to resources.

Social Neglect and Poverty

By positioning poverty as a contributory factor, social, community, and institutional forms of neglect are highlighted (Garbarino and Collins, 1999; Lawrence and Irving, 2004). As Garbarino and Collins (1999: p. 17) argue "we already know that rates of neglect are higher among poor people. So when

society ignores them, it contributes to child neglect." Institutional policies that ignore the needs of children become a form of institutional neglect (Garbarino and Collins, 1999). Dubowitz (2007) argues that poverty in itself is a form of social neglect. Hence, the neglect of children "becomes not simply an indictment of those families which fail to meet the basic needs of their children, but also of a society which fails to construct and maintain an infrastructure which facilitates parenting and values children" (Stone, 1998: p. 95).

An ecological conceptualization of neglect (Dubowitz et al., 1993: p. 10) recognize that "although parents are responsible for nurturing and protecting their children, social factors influence their ability to provide that care." An ecological approach would allow for the "*shared responsibility* among individuals, families, communities and society. Replacing individual blame by a shared responsibility enables a more constructive approach, and suggests interventions be targeted at multiple levels" (Dubowitz et al., 1993: p. 15). Similarly, Turney (2000: p. 54) advocates that social workers rethink the concept of care, taking into account the political and social contexts in which it takes place: "a more holistic account of the process and relationships of caring reduces the likelihood of a simple mother-blaming response to neglect and promotes the chance of a response based on support." For example, Swift (1995) found that reference to social and economic issues did not appear on case files pertaining to neglect, with child welfare rooted in the private family and obligation of parents to provide for children within the family structure: "the organization of records provides a format for noticing and collecting information that simultaneously reflects and supports the personalised stream of discourse about neglect and not the discourse to do with poverty" (Swift, 1995: p. 95).

Conclusion

This article has highlighted how the 'neglect of neglect' has been challenged through recognition of its increased incidence and evidence of its adverse effects on children. Definitions of neglect are varied and contested and can be defined narrowly and more broadly. It is recognized that neglect is complex, multifaceted, and difficult to define. However, common to most definitions is the persistent parental omission of care, a failure to provide, and to meet a child's basic needs. There is an emphasis in practice on physical neglect, viewed as observable and visible and easier to prove in court and in legal terms. The literature also highlights that given the complexities of defining neglect, the point at which care becomes inadequate is difficult to ascertain. The notion of 'good enough' parenting is contested. The range of studies that explore the characteristics of neglectful parents, including mothers' personalities, caring attitudes, relationship and attachment history, and risk factors for neglect have also been discussed. This article has explored the major discourses and contextual issues that have emerged, including neglect and poverty and the gendered nature of child neglect and policy responses.

Abstract

This article will provide an overview of the international policy context of child protection. It will identify current trends in a range of countries. The key tension between promoting child and family welfare and ensuring child protection is discussed in these contexts. The article then discusses the practice issues of risk assessment and the skills required in child protection work. It will conclude by examining the child protection issues faced by black and minority ethnic children and disabled children.

Introduction

This article describes the international policy context of child protection before discussing key elements of risk assessment and skills required in practice and will conclude by highlighting key debates in the area.

The International Policy Context

The United Nations Convention on the Rights of the Child (UNCRC, 1989) established internationally agreed standards for children's rights. All but two countries, Somalia and the United States, have ratified the convention. While all 54 articles have implications for child protection, Article 19 'Protection from all forms of violence' is the most relevant article to explore in this paper. This article states:

1. States Parties shall take all appropriate legislative, administrative, social, and educational measures to protect the child from all forms of physical or mental violence, injury or abuse, neglect or negligent treatment, maltreatment or exploitation, including sexual abuse, while in the care of parent(s), legal guardian(s), or any other person who has the care of the child.
2. Such protective measures should, as appropriate, include effective procedures for the establishment of social programs to provide necessary support for the child and for those who have the care of the child, as well as for other forms of prevention and for identification, reporting, referral, investigation, treatment and follow-up of instances of child maltreatment described heretofore, and, as appropriate, for judicial involvement (UN General Assembly, 1989 Article 19: p. 7).

In 2011, the United Nations Convention on the Rights of the Child (UNCRC) established CRC General Comment 13 (GC13). The aim of GC13 was to provide clearer interpretation of Article 19 by establishing measurable indicators regarding outcomes for children, thereby strengthening child protection at all levels in every country.

The relationship between the UNCRC and national legislation varies across countries. For example, at a European level, the UNCRC is not formally incorporated into the European Convention on Human Rights (ECHR 1950), although some elements are included. Nations who ratify the treaty are bound to it under international law and are known as State Parties. However, full integration of the principles is not always evident in national legislation. In the UK, for instance, all policies must be compatible with children's rights as outlined in the UNCRC. However, although there have been attempts to harmonize the UNCRC with UK national legislation, it has not been fully incorporated. Since 2004, a Children's Rights Index has been established for over 190 countries to monitor the implementation of children's rights at national level (see Gran, 2010 for an overview). The UNICEF commissioned report (Lundy et al., 2012) provides an overview of how the UNCRC has been incorporated into domestic legislation in 12 countries with an in-depth analysis of implementation in 6 of these countries. The report also examined nonlegislative means by which nations may fulfill their duties under the convention including independent human rights organizations, national strategies, visible cross-sectoral coordination, child impact assessment, budgeting, data collection, training and awareness, and participation.

There are significant differences in how governments interpret their statutory duties to protect children. Gilbert et al. (2011) argue that there are typically two orientations toward child protection practice, one which focuses on child protection and is typified by concentration on investigation and the establishment of whether or not abuse has taken place, and a second which takes a family service approach based on assessment of need and typically leading to a therapeutic response. They argue that Anglo-American countries tend to take a child protection response, while European and Nordic countries broadly favor a family service response. However, there are significant variations within these broad approaches.

Within the child protection-based jurisdictions, there are different approaches to mandatory reporting (see Gilbert et al., 2011). There is mandatory reporting in Canada, Australia, and in some American states. However, there is no mandatory reporting in the United Kingdom and New Zealand. The countries, and states within countries, differ with regard to the existence of national guidance and procedures, and the use of specific assessment tools. Furthermore, there are different trends developing in each country. In England, following a major review of child protection (Munro, 2011) there has been a shift from a child protection orientation, toward one of

prevention. In the US, differential responses to child protection concerns are developing and in some states where the family group decision-making model from New Zealand has been introduced (Duerr Berrick, 2011), while in Canada there has been an intensification of the child protection model, although, parallel to this development, Canadians have also adopted family group conferencing (Swift, 2011).

Similar differences exist between Nordic and continental countries, which use a broader family service approach. In Sweden and Finland, while child protection work is located within child and family welfare services, there is mandatory reporting. Additionally, there is a growing concern that the Swedish state intervenes too quickly (Cocozza and Hort, 2011). Similar debates are taking place in other parts of continental Europe. For example, Wolff et al. (2011) argue that the German system fluctuates between strengthening the child welfare approach and adopting an investigatory risk assessment approach. The Belgian response to child and family welfare concern has historically been based on principles of social responsibility but this approach could be under threat in the future, following cases such as the Dutroux Case in 1996 after which public demonstrations took place to demand that more attention be paid to the child and for more substantial professional and judicial responses (Desair and Adriaenssens, 2011).

A different pattern emerges in the developing world where "sophisticated child abuse services are a relatively recent phenomenon" (Lachman and Poblet, 2002: p. 588). Moreover, the focus of child protection research and practice has been on issues such as poverty (Egibo, 2002), children affected by HIV/Aids (Nyandiya-Bundy and Bundy, 2002), and children affected by war and displacement (Killian, 2002).

Lachman and Poblet (2002) argue that

> Intrafamilial abuse must be addressed by child protection services that have a comprehensive and holistic approach and therefore services should also tackle extra-familial abuse … The poverty of the South should not negate the development of child protection services. Rather it should encourage the development of a different model, where child protection services exist despite war and death, where they are enmeshed within the services of a community, and where the participation of the community itself and children is seen as paramount.
> (p. 591)

In a similar vein, following a detailed statistical analysis of the consequences of child maltreatment in high-income countries, Gilbert et al. (2011) argue that international comparative studies outside of North America and northern Europe are needed "to help learn lessons from different settings about how to prevent child maltreatment and its consequences" (p. 10). They suggest that the changing patterns in child maltreatment between countries require further investigation. For example, one significant difference between high-income countries and developing countries is what appears to be a decrease in high-income countries of physical and sexual abuse. What lessons could be learned from this trend, which could inform child welfare and protection services in developing countries? They suggest further research is also needed into the characteristics of families, and communities and services, which promote health development in children (see this study for detailed statistical analyses of incidence and prevalence).

Some of this comparative research is being undertaken by the International Society for the Prevention of Child Abuse and Neglect, which produces a text on world perspectives on child abuse every 2 years (Dubowitz, 2012). This is informed by findings from a 2012 World Perspectives Survey completed by 69 countries, representing 77% of countries where the researchers were able to find a potential respondent. As the author acknowledges, the report offers a "somewhat representative view of the state of child protection-across different regions of the world and according to countries' income levels" (Dubowitz, 2012: p. 5), making the findings an important source of cross-country comparisons. It offers information on how child maltreatment is defined in different countries, some insight into incidence and prevalence rates, the surveillance of child maltreatment and current responses to child maltreatment worldwide. The survey found that the most common forms of maltreatment considered to be child abuse and neglect were physical and sexual abuse (incest, sexual abuse, or pornography). Eighty percent of respondents also cited other issues like failure to provide adequate food and clothing, sexual exploitation, and forced labor. One of the behaviors mentioned least by respondents was that of physical discipline. While this was of concern to countries in northern Europe, it did not feature significantly in responses from Oceania and Africa. Child abandonment was also not uniformly considered to be a form of child maltreatment.

With regard to surveillance and responses to child protection, the survey found that the formal documentation of cases of child maltreatment was becoming widespread, with 54% of respondents reporting that their country maintained official statistics on reported cases and 90% of countries reporting that their country had an official policy regarding child maltreatment. Surveys were completed by 69 countries with 10 respondents from Africa, 10 from the Americas, 27 from Asia, 20 from Europe, and 2 from Oceania. Mandatory reporting by professionals had been established in the countries of 92% of respondents, specific criminal penalties in 90% and provisions for removing children from their parents and carers in 87%. However, while the existence of policies is encouraging, only one-third of respondents considered the policies to be comprehensively implemented in practice. Furthermore, while the researchers found that services such as home visiting and therapy were developing across all countries, very few services were deemed adequate with low income and African countries reporting the least resources.

Critical Issues in Child Protection Practice

Risk Assessment

At the centre of debates across countries is that of the nature of risk assessment in child protection. Child protection guidance differs according to country, depending on how risk is defined, if at all. Risk is not a quantifiable entity and professional judgment is core in the assessment of risk. Parton (1997) has long argued that the social work response to child protection

concerns have been overly risk averse, and intervention and responses to intervention have been characterized by a focus on blame and culpability.

However, analyses of child protection interventions, which were not successful and where a child has been severely harmed or killed, have identified some common failures with regard to risk assessment. Although there have been individual errors where social work services are involved, a common feature of cases of child death or severe injury has been related to errors of reasoning when social workers are faced with large quantities of information and have to make decisions in the context of confusion and chaos (Munro, 2011; Brandon et al., 2008, 2009). Research has found that professionals are prone to make certain errors when undertaking child protection assessments. They are more likely to take account of verbal information that is easily available to them, both at the beginning and of the assessment process (Munro, 1999). Practitioners are also more likely to take account of information, which is striking; so they are more likely to focus on visible information. Therefore, less-specific referrals, for example, involving neglect or emotional abuse, are given lower priority although such referrals are likely to result in the child suffering more harm. In a significant proportion of cases, it has been found that social workers have failed to assess the past history of families and so have missed significant patterns of behavior.

In the light of these concerns, one response has been the development of risk-assessment tools, procedures, protocols, and guidance for practice. These tools and guidance allow for sharing of information on what had been found to be a successful intervention and provide a structure for social work assessments (Munro, 2010). However, there are concerns that overdependency on such tools may result in a rigid responses in which the child does not remain at the centre of good child protection practice. Overemphasis on performance indicators may result in attention being concentrated on the most easily accessible and understood quantitative data, which then runs the risk of workers avoiding the analysis of complex qualitative information. These tools may also give a false sense of objectivity and accuracy, when the evidence of the accuracy of the predictive capacity of these tools is not conclusive. They may undermine the professional skills, autonomy, and judgment of those engaged in child protection work (Munro, 2011).

Skills in Child Protection Practice

Research and inquiries into child protection cases have identified the core cognitive and practice skills required by child protection workers. Attention has been paid to the importance of workers gathering historical information to build a family chronology through which patterns of behavior can be viewed over time. From whom workers gather information is crucial, and research has found that too often workers direct their attention to working with parents who are leading chaotic lives, often linked to domestic abuse, mental health and addiction issues, at the expense of seeking the views of children (Brandon et al., 2008, 2009).

A key issue in a number of inquiries has been parental deceit and feigned compliance (Brandon et al., 2008, 2009). Munro (2005) gives a frank statement on the crux of the matter:

> Professionals dealing with a concern of child abuse need to operate with a higher level of suspicion than usual: parents are anxious to hide abusive behaviour [and] are likely to be dishonest.
> (2005: p. 379)

Fauth et al.'s (2010) scoping study of research between 2000 and 2009 into effective practice to protect children living in families where parents are highly unwilling to engage with support services identifies that professional empathy and a focus on relationship building with parents needed to be balanced with an 'eyes wide open' approach in which professionals retain an authoritative stance. This involves social workers dealing openly with issues of power in the relationship while at the same time involving the family in identifying appropriate methods of support. Brandon et al.'s research (2008) identified a pattern of workers being overwhelmed by the complexity of such cases and developing a strategy of concentrating on the present, ignoring past history and being over optimistic at small changes in the parental situation or attitude, resulting in a 'start again syndrome' (p. 324).

However, although overattention to parental issues has been found to result in poorer outcomes for children, developing appropriate partnerships with parents where there are child protection concerns is an essential skill in child protection work, and the difficulties of developing effective partnership working with parents have been highlighted in a number of studies (Brandon et al., 2008; Fauth et al., 2010). Balancing building a relationship and developing critical analysis of the situation makes great demands on social workers' communication skills. Forrester et al. (2008) found that social workers had a tendency to engage in high levels of confrontation and display poor levels of listening when trying to discuss child protection concerns with parents. The authors found little evidence of workers empathizing with the parental viewpoints and argue that those who did form empathic relationships were able to raise, concerns, which could then be addressed in partnership.

There is some evidence that social workers can effectively build good working relationships with parents when there are child protection concerns. Spratt and Callan's (2004) study found that parents were very positive about the ability of workers to empathize and communicate with them. They found that a key feature of effective practice is the ability of the worker to be clear to parents about initial concerns they have in relation to issues of inadequate parenting in order that effective work on addressing the concerns could take place quickly and in partnership.

There has been a longstanding concern about the gendered nature of child welfare and child protection processes (Daniel and Taylor, 1999; Dominelli, 2002; Milner, 1993). With regard to working with mothers in the child protection process, several authors have emphasized that the majority of mothers in the child protection process are single mothers living in poverty and deprivation. They argue that child welfare services have taken a punitive approach to marginalized and disadvantaged young mothers who are subject to

excessive policing and surveillance (Dominelli et al., 2005; Rutman et al., 2002; Strega et al., 2008).

A number of reasons have been suggested to explain the absence of fathers from the child protection process. A fundamental issue is the predominant discourse of fathering, which it is suggested is viewed as having a higher status than mothering (Milner, 1993) and characterized as providing financial support rather than undertaking caring responsibilities with children. Fathers are perceived as being absent or dangerous, and work with fathers is not seen as core business of social work (Dominelli, 2002; Scourfield, 2006).

Although there is some research evidence to suggest that fathers want active roles in child welfare processes (Dominelli et al., 2011), there is little concrete evidence on what promotes engagement with fathers. However two literature reviews in this area conclude that early engagement, persistence, direct work with fathers, the provision of relevant and flexible services, and worker training are essential (Maxwell et al., 2012; Zgoni et al., 2013).

The failure to engage with children effectively in the child protection process has also been identified as a feature in a number of inquiries, which suggests that workers usually only take account of children's views where they supported the workers assessment of the situation. It has been argued that taking children's views seriously is a fundamental protective mechanism (Munro, 1999; Laming Report, 2003). Children are generally unclear about the child protection process in which they find themselves, and workers tend to underestimate the ability of children to express their view and be involved in decisions about them. Core skills of communicating with children are, therefore, the foundation of child protection practice and this requires workers being able to build relationships over a period of time. This is very difficult given the urgency of some child protection work and the imperatives of time scales for assessment and investigations in many child protection procedures.

Developing Understandings

Black and Minority Ethnic Children

There are two areas that are striking in the research in this field. The first is the concern raised about the treatment and status of child protection work with the indigenous population of countries of the Australia, Aotearoa/New Zealand, Canada, the United States, and Europe. Historical displacement and discrimination has led to current major concern with regard to child welfare and child protection for these diverse populations (Haig-Brown, 1988; Libesman, 2012). A report in Australia (2007) revealed the widespread violence and sexual abuse of women and children in the Northern Territory (Wild and Anderson, 2007). Oliver (2012) argues that intergenerational trauma and dysfunction, disadvantaged living conditions, alcohol and substance misuse, and the use of pornography are key elements in the maltreatment of Aboriginal children. She suggests that victims may be unable or reluctant to come forward to give evidence for fear of ostracism from the community.

With regard to indigenous communities in New Zealand, Taaouni (2012) argues that "Maori are experiencing a four – decade cultural renaissance marred by several horrific Maori child homicides" and that "Debate has raged around causes and solutions" (p. 161). She states that some commentators argue that these events are a result of inadequate Maori parenting and a 'warlike' society. Others argue that the abuse of violence is exaggerated and that abuse arises from the colonization of Maori culture. Therefore, social, economic, political, and cultural processes have established a context for violence (see Tait-Rolleston and Pehi-Barlow, 2001 for discussion on Maori social work).

In respect of the North American continent, the over-representation of Aboriginal children in child protection statistics, and out-of-home placement in Canada has been attributed to the multiple disadvantages experience by Aboriginal families such as socioeconomic factors (Trocme et al., 2004). For example, the poverty rates of Aboriginal children in Canada in 2000 was 41%, whereas the total poverty rate for children was 19.1% (Swift, 2011). Similarly, in the United States concern had been expressed about the major policy issues, which have not been addressed in the field of child welfare, leading to Native American children not being afforded the same rights of protection and welfare that is given to other children in the United States (Cross et al., 2000).

The UNICEF (2012) report on the implementation of children's rights in 12 countries provides a succinct summary of the issues for these groups of children:

> In all countries in the study, the most vulnerable groups of children (separated children, asylum seekers and indigenous children and asylum seekers and indigenous children and children in conflict with the law) continued to fare less well compared to peers. This was linked to higher levels of poverty and social exclusion, concerns that have increased significantly in recent years. In several countries interviewees suggested that separated children and asylum seekers were not seen as rights holders in the same way as other children, and this was linked to the weakness of the CRC in these areas.
>
> (Lundy et al., 2012)

In the Europe and North American context similar concerns emerge with regard to child protection services to black and minority ethnic children and families. In the UK, there is evidence to show that black and minority ethnic children are over-represented on child protection registers, placement in local authority care and referrals to child protection teams (Barn, 1993). There is a debate about why black and minority children are overly represented in child protection statistics, with some commentators citing parenting traditions and others the impact of institutional racism on black and minority ethnic children and families (Ahmed, 2005; Chand and Thoburn, 2006). Black and minority ethnic families are more likely to live in poverty, which is a significant indicator of the possibility of child maltreatment, particularly in the case of neglect (Dominelli, 1997; Stokes and Scmidt, 2011). The failure to acknowledge issues of race, language, culture, and religion are noted in a number of the analyses of child deaths (Brandon et al., 2008). Concern has been expressed about the overpathologizing of black and minority ethnic parents by professionals (Chand, 2000). However, more attention is paid in the literature to the concept of 'cultural

relativism' among professionals working with black and minority ethnic families (Barn, 2007; Laming Report, 2003). Cultural relativism is the process by which professionals make assumptions about cultural practices and accept different standards of care, as it is assumed that these practices are viewed as culturally acceptable in the family's community. Furthermore, cultures may be viewed as having a homogenous identity and the different cultures in which the child is embedded can be ignored, for example, the childhood culture, family culture, geographical culture, and religious and linguistic cultures (Connolly et al., 2005). Finally, systemic issues in safeguarding or child protection processes, where policy and procedures fail to address the needs of black and minority ethnic families are viewed as an important factor in the overrepresentation of black children in the child protection system (Chand, 2008).

There is a further issue regarding asylum-seeking children in Europe (Cardol, 2012), Canada (Ayoke, 2001), Australia (Bhahba, 2007), and North America (Molina, 2012; Somers et al., 2010). Child protection systems need to take into account the additional stresses faced by refugees and asylum-seeking parents, who may have experienced violence and persecution in their home country and then endure persecution, suspicion, and racism in their host countries (Cardol, 2012). Social work responses to the particular challenges of working with unaccompanied asylum-seeking children are a further area for practice development (Hill and Hopkins, 2009).

Disabled Children

The needs and rights of disabled children in need of child protection is an underresearched area. In an international literature review of disabled children and child protection, Stalker and McArthur (2010) identified 38 relevant studies. Overwhelmingly, the studies found that disabled children are more likely to be abused than nondisabled children. Evidence was found of underreporting of abuse of disabled children (Cooke and Standen, 2002; Hershkovitz et al., 2007). The correlation between the types of abuse and types of impairment was inconclusive, but the authors found that the evidence suggests that children with communication impairments, behavioral disorders, learning difficulties, and sensory impairments were more vulnerable to being abused. Evidence on the direction of causality, the extent to which maltreatment contributes to impairment or whether impairment predisposes children to abuse is also inconclusive.

Stalker and McCarthur (2011) found a 'complicated and inconsistent' (p. 9) pattern with regard to the gender of disabled children who had been abused. A similar inconsistent pattern was found with regard to the role of cultural and social factors, but with very little research in this area the authors considered it unwise to draw conclusions. However, Kapitanoff et al. (2000) argue that definitions of abuse vary across cultures, and prevalence in some black and minority groups may be confused by the fact that black and minority ethnic children are more likely to be in lower socioeconomic groups, which as shown above, is positively correlated with child maltreatment. Few studies had asked disabled children about their experiences of being abused or being involved in the child protection system. Similarly, they found a dearth of research, which examined professional responses to the abuse of disabled children or the effectiveness of child protection services for these children.

Conclusion

This article has given an overview of the key concerns facing policy makers and practitioners in the field of child protection in an international context. A key issue for policy makers is to ensure that the UNCRC is fully integrated into domestic law and policy. Evidence shows that where this is the case, children's rights are more fully upheld. Participation of children in decision making is a key element in ensuring children's rights. While progress has been made with regard to listening to children and ascertaining their views, participation of children is an underdeveloped area. At a practice level, social workers can contribute to upholding children's rights to be protected and to participate in decisions by ensuring children are listened to and encouraged to voice views and enabled to participate in decision-making processes. The UNCRC is an international mandate, which nations and countries can utilize to ensure children's rights and views are upheld.

Child Protection: International Issues

Simon Hackett, Durham University, Durham, UK

Abstract

This article considers the controversies, debates, and challenges associated with promoting children's welfare and ensuring their protection from abuse and harm. An overview of child protection as a concept and a practice is offered. Key concepts and definitions are examined emphasizing the contested nature of child abuse. Current issues in child protection theory, research, and practice at the international level are explored including the need to protect children in situations of 'natural' disasters and emergencies, as well as in political conflict and war. The global challenge of protecting children from sexual abuse and exploitation in the context of new technologies is also considered.

Introduction

Examples of the ill-treatment of children exist throughout history and across cultures, including infanticide, abandonment, forced marriage, child labor, and sexual exploitation. While the standards of care afforded to many children in previous centuries may fall short of those considered to be necessary in the present day, there is, at the same time, considerable evidence that children have been valued, nurtured, and cared for in every era:

> Every society has to deal with the issue of the care of its young and has devised some means of intervention into family life to ensure this. These efforts have been influenced by the cultures, material circumstances, technologies and politics impinging on those societies. (Corby, 2000: p. 20)

This article explores the controversies and debates associated with such efforts in order to offer an overview of child protection as both a concept and a practice. It begins by exploring and clarifying definitions before examining some of the key changes in focus in protecting children, as well as current challenges and emerging directions in child protection theory, research, and practice. While most attention previously has been given to child protection at the level of the individual state, the processes of globalization have brought about, now more than ever before, cross national issues which threaten the welfare and development of children. For example, the Pinheiro's (2006) *World Report on Violence against Children* for the United Nations found that physical violence against children in the home is widespread in all regions of the world and estimated that each year worldwide 150 000 000 girls and 73 000 000 boys experience sexual violence; 1 800 000 children are involved in commercial sexual exploitation and child abuse images; and 1 200 000 children are victims of trafficking. This means that child protection is no longer merely an issue that individual societies have to address, but a global concern. Therefore, this article focuses on child protection internationally as a complementary chapter to a further article in the Encyclopedia which primarily addresses the child protection system in the United Kingdom.

Definitions

Defining what is meant by 'child protection' and associated concepts such as 'child abuse,' 'welfare,' 'harm,' and even 'childhood' is a complex and contested activity. This means that conceptualizing child protection issues is fraught with definitional dilemmas and complexities. It is, therefore, vitally important to debate and clarify what is meant by the various terms associated with this field of practice to understand child protection at the international level.

Defining Childhood

Childhood itself is a social construct rather than a fixed biological period, with the rights and protections afforded to children and young people of particular ages and stages of development at times highly variable and contradictory (Ariès, 1962). For instance, the age at which children are held criminally responsible, can have sexual intercourse, are entitled to marry or vote has shifted throughout history and still varies considerably across, and even sometimes within, nation states. The United Nations (UN) (1989) *Convention on the Rights of the Child* defines a child as a person below the age of 18, unless the laws of a particular country set the legal age for adulthood younger. The UN Committee on the Rights of the Child, the monitoring body for the Convention, recommends that states where the age of majority is set below 18 should increase the level of protection for all children under 18.

Defining Children's Rights

Built on varied legal and cultural traditions, the UN *Convention on the Rights of the Child* provides a universally agreed set of non-negotiable standards and obligations for those nations who are signatories. The Convention outlines the fundamental rights of children, including the right to be protected from economic exploitation and harmful work, from all forms of sexual exploitation and abuse, and from physical or mental violence, as well as establishing that children should not be separated from their family against their will. Specifically, Article 19 of the Convention sets out

children's rights to protection from all forms of violence in the following terms:

> Children have the right to be protected from being hurt and mistreated, physically or mentally. Governments should ensure that children are properly cared for and protect them from violence, abuse and neglect by their parents, or anyone else who looks after them…. In most countries, laws already define what sorts of punishments are considered excessive or abusive. It is up to each government to review these laws in light of the Convention.

Additionally, Article 34 states that:

> Governments should protect children from all forms of sexual exploitation and abuse.

The UN Convention is widely acknowledged as the most complete statement of children's rights ever produced and is the most ratified international human rights treaty with all UN member states except for the United States, South Sudan, and Somalia having approved it. As such, it provides a useful foundation for the building of a theory and a practice of international child protection. At the same time, however, the Convention has generated continuing debate, with opponents fearing that ratification could undermine individual nations' sovereignty and interfere in the private lives of citizens (see Gran, 2010). Others have argued that simply adopting the UN *Convention on the Rights of the Child* does not guarantee the protection of children's rights in real-world situations (Blanchfield, 2013). For example, it has been noted that some countries widely criticized for abuses of children's rights, such as the Democratic Republic of Congo, China, and Sudan, are signatories (Blanchfield, 2013). Even a country such as the United Kingdom, where the notion of children's rights is well established socially and embedded within social policy and social work practice, has an ambiguous track record on ensuring the rights of *all* children. The UK government has been criticized for breaching some of its human and children's rights obligations in the way in which it approaches children involved in the asylum system (Clements, 2006) or in the way that young offenders are transferred from youth custody to adult prisons (Puffett, 2013). Additionally, Blanchfield points out that a number of Islamic countries have attached reservations to their adoption of the UN Convention which state that ratification would not apply to provisions that they deem incompatible with Islamic Shari'a law or values. She adds that this raises concern that such reservations could allow for broad interpretations of the Convention's provisions, particularly in the area of child marriage and education for girls (Blanchfield, 2013: p. 16). Ultimately, the most significant limitation of the Convention is not the rights it enshrines, nor its ability to influence legislation in those nations endorsing it, but the variability of actions which flow from such legislation in protecting children and their rights.

Defining Child Abuse

While the UN *Convention on the Rights of the Child* sets out the rights of children to be protected from all forms of violence and abuse, as outlined earlier, it does not offer definitions of specific types of abuse or the range of behaviors that might constitute them. This too is a contested and difficult area. Child abuse is as much as a social construct as is the concept of childhood (Corby, 2000). What are deemed to be optimal, acceptable, or abusive parenting practices vary considerably over time and across and within cultural contexts. For example, in some jurisdictions, the use of parental corporal punishment as a means of disciplining children is viewed as harmful and is outlawed, while in other cultures, it is seen as a necessary and responsible way of raising children. According to the World Health Organisation (WHO, 2013):

> Child maltreatment, sometimes referred to as child abuse and neglect, includes all forms of physical and emotional ill-treatment, sexual abuse, neglect, and exploitation that results in actual or potential harm to the child's health, development or dignity. Within this broad definition, five subtypes can be distinguished – physical abuse; sexual abuse; neglect and negligent treatment; emotional abuse; and exploitation.

The above-mentioned definition is one of thousands on child abuse that have been proposed internationally. The discrepancies and inconsistencies between them reflect real and, at times, deeply conflicting social values and standards relating to the state's role in intervening in the lives of its citizens. Nonetheless, there is now considerable support for the five subtypes of child abuse included in the above WHO definition. The development of these core categories of child abuse is, in large part, the consequence of the long history of social workers and other professionals being confronted with ever more complex and diverse cases where children have been harmed. This has forced appraisal and reappraisal of the nature and range of abuses faced by children. For example, it is widely stated that awareness of child abuse in the modern era stemmed from the ground-breaking work in the 1960s of American pediatrician Henry Kempe and colleagues who outlined the term 'battered child syndrome' thereby bringing the issue of child physical abuse into the professional and public consciousness. However, it was not until a decade and a half later until survivors of child sexual abuse began to raise awareness of this 'new' form of abuse (Amstrong, 1978). Awareness of emotional abuse and neglect followed yet later (Garbarino et al., 1986). The nature of sexual abuse perpetrated by children and young people (Hackett, 2004) and the abuse of children in institutions, such as the well-documented series of cases of abuse within the global Catholic Church (Keenen, 2012), are even more recent developments.

It is also necessary to operationalize each of the five subtypes of child abuse within national policy, legislation, and guidance. In the United Kingdom, this guidance comes in the form of the *Working Together* document which was first published in 1988 (DHSS, 1988) but which has been updated at regular intervals until the most recent iteration in 2013 (HM Government, 2013). While the categories or subtypes of abuse included in these documents have remained largely static, the accompanying guidance has been expanded considerably and the definitions of each abuse category has shifted considerably

as new knowledge and better research evidence about the nature of the form of abuse has been generated. In addition, there is a further complexity faced by social workers who need to work with general categories of abuse in their practice and make decisions about whether the circumstances of individual cases fall within these categories and, importantly, what action is therefore warranted. Defining and redefining child abuse, it appears, is a continual process.

Defining Child Protection

Finally, in terms of definitions, increasing awareness and a body of practice knowledge and empirical research about the various subtypes of child abuse has led to the development of a particular strand of social work practice which has become known as 'child protection.' 'Child protection' is a term that describes the philosophies, policies, standards, guidelines, and practices that guide when to, and how to, intervene in the lives of children in order to ensure their protection from these various types of abuse and maltreatment. While social workers do not have a monopoly on child protection practice, with professionals such as doctors, teachers, psychologists, and the police integral to the child protection task, child protection represents a field of social work practice that is recognized, and recognizable, internationally. For example, a review of published research within the last 2 years in the journal *International Social Work* reveals papers addressing child protection issues in the following diverse countries: Nigeria, Uganda, China, India, Brazil, El Salvador, Guatemala, Nepal, Sierra Leone, Turkey, the United Kingdom, and the United States. While all countries have some sort of child protection system, it is however clear that some are more developed and better resourced than others. It is important that each country develops its own approach taking into account tradition, culture, and the specific challenges it faces (Ortiz et al., 2012). Each country should identify the way in which social workers should respond to these challenges, while at the same time clarifying the child protection responsibilities of other professional groups. It is increasingly acknowledged that it is vital to involve those who are on the receiving end of child protection services, both children and parents and carers in this process, not least because their rights and their experiences have been overlooked in the past.

UNICEF (2006) defines eight components necessary for the building of protective environments internationally that will prevent and respond to child abuse, including actions across societal, governmental, and professional service levels:

- Strengthening government commitment and capacity to fulfill children's right to protection;
- Promoting the establishment and enforcement of adequate legislation;
- Addressing harmful attitudes, customs, and practices;
- Encouraging open discussion of child protection issues that includes media and civil society partners;
- Developing children's life skills, knowledge, and participation;
- Building capacity of families and communities;
- Providing essential services for prevention, recovery, and reintegration, including basic health, education, and protection; and
- Establishing and implementing on-going and effective monitoring, reporting, and oversight (UNICEF, 2006: p. 1).

Social workers' specific responsibilities in relation to these tasks vary considerably according to how their professional roles are conceived in different countries, but often they are central to the identification of cases of abuse and in the provision of services to help children recover from their experiences.

Current Challenges in Protecting Children at the International Level

Such is the diversity of factors associated with the abuse of children internationally that it is impossible here to offer a comprehensive list of the challenges currently facing the international community. Instead, a number of key indicative themes are presented which illustrate the challenges that social workers face internationally in their attempts to improve the protection of children in the communities in which they work.

Child Protection in the Context of Disasters and Emergencies

The United Nations estimates that 66 million children around the world are affected every year by 'natural' disasters such as floods, earthquakes, and drought. Dominelli (2012) points out that the term 'natural disaster' is problematic as the behavior of human beings strongly influences the occurrence of what are seen as naturally occurring crises and disasters. Child protection is a particular concern in situations of emergency and humanitarian crisis. Many of the specific elements that underlie such crises, such as displacement and poverty, bring with them specific risks to children. The likelihood that children are vulnerable to the range of forms of child abuse discussed earlier is heightened in situations of natural disasters. Disasters can undermine community and family structures and large numbers of children can become orphaned or separated from their families without warning. Even where children are not separated from their parents as a consequence of disasters, families may be projected into situations of serious unpredictability and can lack access to their most basic needs, such as food and shelter. In such conditions, children may become vulnerable to neglect or exploitation and experience acute stress responses and profound loss. Their education can become disrupted and their development delayed. Girls may be particularly vulnerable to sexual abuse during emergencies. For example, research in Bangladesh and Ethiopia has indicated that risk of sexual violence and forced marriages increases for girls during and after disasters (Swarup et al., 2011).

Social workers play an important role in stabilizing the conditions in children's lives in the aftermath of disasters and restoring the conditions necessary for survival, recovery, and growth. For example, Sim et al. (2013) outline the critical role played by social workers in the aftermath of the 2008 Wenchuan earthquake in China. Here, it is estimated that over 1000 social workers were involved in immediate rescue efforts and the subsequent reconstruction of damaged communities. Social workers worked to develop community

cohesion, support parenting, and offered direct counseling to children.

Nonetheless, despite some good examples of practice, there is a general lack of connection between the orthodox practices associated with humanitarian aid and those involved in protecting children. As Ridsdel and McCormick suggest:

> Despite the heightened vulnerability of girls and boys during and after conflict and disasters, currently humanitarian action does not give adequate priority to child protection and care, a situation that reflects the broader lack of attention given to this important issue in fragile and non-fragile states. (Ridsdel and McCormick, 2013: p. 3)

This is further compounded by many states in the global South that are particularly vulnerable to natural disasters having underdeveloped child protection systems. As well as calling for social work educators to develop more systematic programs of training and education in disaster social work (Sim et al., 2013), it is important to develop awareness among social workers of the child protection implications of disasters so that addressing such needs becomes a core element of the practice of social work interventions in disasters. This is particularly the case given predictions about the likely future increase in the frequency, severity, and unpredictability of disasters. For instance, Save the Children (2009) predicts that every year over the next decade 175 million children will be affected by disasters brought about by climate change across the world. Perhaps then, climate change poses the biggest challenge to child protection at the global level. In this way, Dominelli's (2012) call for the social work profession to move to a new model of 'green social work' is echoed in the need for a 'green child protection practice' that sees protection of the environment as a fundamental element in preventing and responding to the abuse of children.

Safeguarding Children Abused in Armed Conflicts

Political conflict, civil unrest, and war violates children's rights and blights their lives in many areas of the world. Political conflict and war is a human, rather than a 'natural,' disaster, created and waged in large part by adult men but with both a direct and an indirect impact on children's development, well-being, and safety (Santa Barbara, 2006). Children are frequently abducted during the course of armed conflicts and displaced from their families and communities, with some being forced into the military against the provision of Article 38 of the UN *Convention on the Rights of the Child* which limits the involvement of children under the age of 15 in any branch of the armed forces. The organization Human Rights Watch estimates that between 200 000 and 300 000 children are serving as soldiers in armed conflicts around the world, with approximately 100 000 of these children fighting in Africa alone. Children are harmed in war as a result of their direct involvement in armed conflicts as soldiers, where they are vulnerable to death and injury, disablement, and emotional trauma. Child soldiers are brutalized through being forced to kill and inflict violence on others, leading them to be both victims and perpetrators at the same time. Kimmel and Roby (2007) describe the use of child soldiers as a form of institutionalized child abuse. Other children abducted in war are sold into physical slavery or prostitution where they are subjected to rape and sexual abuse. Children who are not recruited directly into fighting are often the victims of war and political conflict. It is estimated that half of all civilians killed in wars across the world are children. Additionally, living in communities bound by war and political conflict is an emotionally disastrous condition for children, breeding insecure attachments and leading to post-traumatic stress, and grief and loss responses. Furthermore, political conflict often exposes children to religious and social intolerance and models the inappropriate use of violence. War is therefore a core and distinct form of abuse of children at the international level.

Social workers are active across the world working with communities affected by war and political conflict. For example, Bhadra (2012) describes support offered to children by professionals and community volunteers affected by communal violence in Gujarat, India. Interventions included working with children in refugee camps using activity-based and narrative approaches that allowed children to tell their own stories of the conflict and its impact, bolstering caregivers' capacities to providing nurturing environments for children, through to the development of community-oriented peace-keeping measures and school-based interventions that promote the values of tolerance and acceptance. Denov (2010) highlights the complexity of responses needed by children involved as soldiers in the decade-long civil war in Sierra Leone. She points to the important role social work should play in protecting children involved in war given the profession's commitment to the empowerment of marginalized communities, but laments that:

> Social work has been largely silent on the issue of children affected by war, and has been suspiciously absent in international debates and discussions concerning war and political violence and related global trends and processes. (Denov, 2010: p. 804)

Protecting Children from Sexual Abuse, Exploitation, and Sexual Trafficking

The sexual abuse of children was traditionally viewed as a domestic crime, perpetrated by adults on children, most often fathers on their daughters (Corby, 2000). However, increasing awareness of differing forms of sexual abuse over the last 30 years has seen social workers' understandings of the dynamics and manifestations of child sexual abuse develop radically. This includes the awareness that a significant proportion of all cases of child sexual abuse are perpetrated not by adults but by children and juveniles (Hackett et al., 2013), knowledge that a significant proportion of victims are boys (Hunter, 1990), as well as the realization that child sexual abuse is not confined to individual homes, but extends to all areas of society and to many institutions (Finkelhor et al., 1988). However, one of the most disturbing features of an increasingly globalized society is the spread of child sexual abuse and exploitation as an issue which now

transcends national boundaries. Not only does child sexual abuse occur in all societies, but the ways in which children are abused and exploited sexually often have international dimensions. These global dimensions contain three major strands: the involvement of children in prostitution; the production of abusive images of children (sometimes referred to as 'child pornography'); and the trafficking of children for the purposes of sexual abuse (US Department of Justice, 2010). The need to protect children from more traditional forms of child sexual abuse continues, but such protective efforts are compounded by, and made more complex as a result of, these globalized features.

Throughout Asia, Latin America, and the countries of the North, there have been increasing reports of growth in the number of children involved in prostitution. There are many factors underpinning this growth, and these factors differ across the world, as does the scale of the problem. In some countries, child prostitution as a phenomenon has existed for centuries, embedded in historical and cultural practices. In most countries, it is brought about as a combination of problems of poverty and socioeconomic inequality, the subordination of women and children, and the perpetuation of attitudes and values that view children as economic commodities (Heiberg, 2001). Approximately, one million children around the world are forced into prostitution every year and the total number of prostituted children could exceed 10 million (Willis and Levy, 2002). Children are frequently trafficked for the purpose of prostitution, either through well-organized criminal networks or through the actions of family members or acquaintances. In some cases, parents or children themselves are lured through offers of a better life or good employment, only to be trafficked into sexual or physical slavery in unfamiliar and alien cultures. Once involved in prostitution, children are also highly vulnerable to rape, physical violence, and a wide range of physical and mental health problems.

Child protection social workers have a role to play in preventing child trafficking through providing increased social welfare and educational opportunities for families at risk, as well as in supporting the rehabilitation of children from prostitution into safe and protective communities. A review of support for trafficked children in the United Kingdom (Franklin and Doyle, 2013) highlights how responses should be primarily dealt with as a child protection issue, with a need for some specialism to ensure that trafficked children's particular needs and circumstances are understood. However, their research into the reality of responses revealed that a lack of understanding among social workers of the immigration system and pressures relating to the immigration process acted as a barrier to supporting trafficked children, as did lack of appropriate placement provision.

Internet Abuse and Online Protection

A final illustrative example of the challenges facing child protection social workers across the world is that of the online abuse of children. The rapid development of new online technologies is a truly transnational phenomenon, even though the availability of such technologies is unevenly spread among children in industrialized as opposed to low-income societies. New information technologies are, however, transforming children's lives in many ways across the world. In terms of child protection, the Internet has significantly increased the availability of information for children about abuse and has provided routes for them to communicate their experiences and gain support. As such, new technologies can challenge the secrecy and isolation brought about by abusive experiences and exert considerable protective influence on children. The widespread use of social media platforms, such as Facebook and Twitter, has networked children in ways not possible previously. At the same time, these new technologies have also brought with them considerable additional risks to children. While new technologies have not created sex offences against children, their use has enabled a shift in the nature and scale of such abuse (Buschman et al., 2010).

Online abuse can include both virtual and actual elements. Livingstone and Haddon (2009) have described the following set of categories to understand risk and harm related to children's online activities:

online harm from content: where the child is a passive recipient of pornographic or harmful sexual content;

harm from contact: where the child is targeted as a participant by an adult or another child in activities such as sexual abuse that is photographed and then disseminated, for online grooming for sexual abuse or for bullying; and

harm from conduct: where the child actively initiates risky or abusive behaviour, for example, by creating or uploading pornographic material, physically meeting an adult encountered online, placing images of herself or himself or another young person online, downloading abusive images of children or bullying.

The range of adult behaviors that constitutes online child sexual abuse includes adults who sexually exploit their own or other children for the production of child abuse images, as well as those who download images for their own personal use. Sex offenders also use online technologies as a way of targeting children for subsequent abuse offline. This includes 'grooming' children online with the intention of abusing them sexually offline. Such approaches may involve the assumption by the adult of a false identity, in particular with the offender pretending to be a child (Whittle et al., 2013). Other forms of online child abuse include children being engaged in sexually explicit talk and being encouraged to perform sexually explicit acts on themselves or their friends.

Given these newly emerging types of sexual abuse of children, online safety is now a major child protection concern. The protection task requires a careful balance between shielding children from harm online on the one hand and their rights for information and for freedom of expression on the other. The law enforcement response in such cases is often very challenging as the behaviors involved are not contained within national borders. An initial sexual offense against a child perpetrated and filmed in the USA and then made available online may be viewed by a network of offenders worldwide. In this example, one initial contact offense may lead to thousands of online offences with the comparative anonymity of the Internet allowing the original offense to be compounded many times over. There are frequently difficulties in the identification of children abused through child abuse images of this kind and

in seeking prosecution of offenders cross nationally (Wortley and Smallbone, 2012).

The development of these new types of sexual abuse of children challenges child protection practices to develop new ways of responding, placing an emphasis on the child protection community to work together with internet service providers to improve safety measures for children and online reporting mechanisms, as well as educating children and parents about the potential dangers of the online environment. The example of the UK-based Child Exploitation and Online Protection Center, which is a world leader in this area, demonstrates the effectiveness of social workers working alongside law enforcement professionals to identify cases where children have been abused online. To play their part in the protection of children from online abuse, social workers need to engage with children in the online environment. Social work has traditionally worked at the heart of service users' social worlds to improve the quality of people's lives in the context of their environment. As children move seamlessly between online and offline social worlds, social workers need to embrace both of these dimensions of children's lives in their protective efforts. Social workers also have a core remit to work with parents to improve their parenting skills and capacities where parenting has been compromised. As such, social workers can educate parents about online risks to children, just as they have done traditionally about, for example, physical risks to children in the home and the external community.

Conclusions

Child protection is not the sole preserve of the social work profession, even though social workers play an important role in safeguarding children from harm across the world. Effective child protection practice requires the sharing of information across professional boundaries and interagency collaboration. Global issues in child protection demonstrate that this collaboration needs to extend beyond the boundaries of individual states. This is a particular challenge to social workers who mainly work within local environments. The variable development of child protection systems across countries, as well as variable levels of awareness about the diversity of issues associated with child abuse, further compounds the challenges and issues associated with international child protection.

Abstract

Child soldiers can be any person under 18 associated with an armed group and fulfilling many roles that may or may not involve combat. An estimated 300 000 children across the globe are members of state militaries and other armed groups. Although armed groups used children throughout history, the widespread availability of small arms has made it physically possible for children to participate in a more lethal combat, thereby increasing their participation value. Children become involved in armed groups through abduction, threats, pressure, and manipulation. Voluntary association also occurs in the context of poverty, gender and ethnic discrimination, and state-sponsored violence. Among published studies of child soldiers, high levels of exposure to violence are reported. Moreover, post-traumatic stress disorder may affect more than half of all child soldiers at some point after association with armed groups. Postconflict factors such as educational and economic deprivation, stigmatization, and discrimination have been associated with adverse outcomes. Reintegration and rehabilitation is particularly difficult for girl soldiers. Potential protective factors for successful reintegration include community sensitization, cleansing rituals, transitional periods in interim care centers, religious support, psychosocial counseling, family mediation, and skills-based vocational training. Policy and advocacy is needed to provide educational and employment alternatives to children in place of joining armed groups; and, regulation and control of small arms trade is needed to reduce recruitment of children by armed groups.

One of the most pressing issues in global conflict is the exploitation of children by armed groups. An estimated 300 000 children across the globe are members of state militaries and other armed groups (UNICEF, 2003). The military recruitment of children has taken place in 86 countries and territories worldwide with approximately half of all child soldiers in African countries (Coalition to Stop the Use of Child Soldiers, 2008). Reflecting this pattern, the vast majority of published research on child soldiers comes from studies in Sierra Leone, Uganda, and Mozambique. Child soldiers are involved in a range of political conflicts such as formally recognized wars, terrorist activities, and ethnic conflict. Although armed groups have used children throughout history, the widespread availability of small arms has made it physically possible for children to participate in a more lethal manner and thus be of greater value to armed groups (Wessells, 2006).

The popular image, often used by organizations to raise funds to support intervention programs for former child soldiers, depicts rogue armed groups violently tearing children away from idyllic family settings and those children as faultless passive victim, psychologically devastated, and irreversibly damaged as a result of conflict. The story continues that these haphazard militias shatter children's lives through the dehumanizing experiences of war, drugs, and crime. These children are also exposed to traumatic experiences and are often forced to commit atrocities themselves. Child soldiers are thus imagined as severely disabled because of the effects of psychological trauma. The final goal for recovery and rehabilitation is the return to and reunification with the child soldier's family.

Although these portrayals do reflect actual cases, the situation of child soldiers is far more varied and complex (Betancourt et al., 2008a; Wessells, 2006). UNICEF and other groups working with child soldiers recognize that children associated with armed groups may assume a range of roles and are not always combatants: the 2007 Paris Principles refer to child soldiers as "children associated with armed forces or armed groups" (CAAFAG) meeting the following criteria:

> any person below 18 years of age who is or who has been recruited or used by an armed force or armed group in any capacity, including but not limited to children, boys, and girls used as fighters, cooks, porters, messengers, spies, or for sexual purposes. It does not only refer to a child who is taking or has taken a direct part in hostilities.
>
> UNICEF (2007): p. 7

Moreover, the reasons that children become associated with armed groups vary considerably. Contexts that promote recruiting children into armed groups are the result of larger national and international processes that produce local vulnerability. Poverty, gender and ethnic discrimination, and legacies of state-sponsored violence create circumstances in which children voluntarily join armed groups. Reintegration is also a complex process that varies widely across different conflicts and can be very different for children in the same conflict. While it might be assumed that removing a child from an armed group is the best approach, it is not a panacea to assure psychosocial well-being. The very focus of *re*integration programs operates with an assumption that former child soldiers were previously *integrated* into their communities. In reality, some child soldiers join armed groups because they feel excluded from society. Reintegration not only means returning back home but also building and sustaining positive relationship, regaining identity, and managing their intrusive thoughts and reveries amidst the stigma they face as former child soldiers (Boothby and Thomson, 2013). Moreover, the tremendous variation in exposure to traumatic events during involvement with armed groups and in resilience among child soldiers throws into question whether psychological trauma is a universal response (Wessells, 2006). Lastly, local definitions

of 'children' vary within and between cultural groups, such that individuals identified as 'child soldiers' by humanitarian groups may locally be considered adults (Kohrt and Maharjan, 2009). This diversity must be considered when understanding the experiences of child soldiers to best inform interventions to prevent recruitment of children into armed groups and to facilitate positive reintegration after leaving armed groups.

Ethical Conduct of Research and Interventions with Former Child Soldiers

Before discussing research and interventions, it is crucial to consider the ethical conduct when working with current and former child soldiers. Child soldiers are victims of exploitation through exposure to military association. Research and intervention should not be another form of exploitation. In conflict settings, research and intervention has the potential to violate the 'do no harm' ethic (Betancourt, 2011; Kohrt et al., 2010a; Wessells, 2009).

Harm can manifest as threats to safety and discrimination of former child soldiers, their families, and their communities. Research and intervention may expose child soldiers who have tried to hide their association with an armed group, thus placing them and their families in danger of revenge by other soldiers or aggrieved civilians. To address this potential harm, the best practices of research and service provision have advocated for working with the broader community, not exclusively focusing on child soldiers. Additionally, participation in research and interventions should not automatically identify a child as a former combatant publicly. A solution to this is the development of research and intervention programs that target a range of vulnerable children, rather than only child soldiers. For example, programs can also work with children with family members who have been targets of enforced disappearance, children whose family members have been tortured, and children in families who have been forcibly displaced. Research also risks stigmatization of former child soldiers (Annan et al., 2011; Betancourt et al., 2010a; Kohrt et al., 2008). Mental health problems carry a strong stigma in most parts of the world (Sartorius et al., 2005). Focusing on normative language related to idioms of distress can give children a therapeutic opportunity to share feelings and emotionally support other children in a nonstigmatizing atmosphere (Karki et al., 2009).

Participatory research is one approach that can help address some of the potential harms when research and intervention programs are dictated by outside actors. Participatory research provides a strong connection between research and intervention salient to the local community. Child soldiers identified psychosocial problems affecting them and processes to address these needs (Karki et al., 2009). The children themselves developed indicators to evaluate the effectiveness of interventions.

Child Soldier Experience in Life-History Context

Understanding the experience of child soldiers requires that the soldier experience be considered in the broader context of life history. Former child soldiers have a range of potential risk and resilience factors related to (1) *presoldier and noncombatant experiences*, (2) *experiences during association with armed groups*, and (3) *postcombatant reintegration experience* (see **Figure 1**).

(1) Presoldier and noncombatant experience

Exposure to trauma and other stressors as a child soldier cannot be considered the sole determinant of psychosocial well-being for former child soldiers. If all children's problems are attributed exclusively to war, interventionists and policy makers risk misapplication of care in resource poor settings (Derluyn et al., 2013). More detailed knowledge of the impact of political violence versus other chronic social problems can lead to better-informed interventions in postconflict settings with scarce resources (IASC, 2007). Children's experiences before becoming a child soldier and the experience of stressors outside of their combatant roles need to be taken into account. One of the important issues is to understand that the threats to child well-being are structural conditions in the presoldier context. Contexts that promote recruiting children into armed groups are the result of larger national and international processes that produce local vulnerability. Poverty, gender and ethnic discrimination, and legacies of state-sponsored violence create circumstances in which children voluntarily join armed groups (Kohrt et al., 2010b). Poverty, especially, is an impediment to well-being of children. Poverty creates risks for violence and exploitation of children.

Countries where children are exploited through involvement in armed group are also likely to be countries where children are exploited for labor in other domains (United Nations, 2005). Children are relied upon heavily for labor in most subsistence agricultural settings. Children are also trafficked to urban centers and other countries for manual labor and commercial sex work. Children have been used for their labor in garment factories, brick manufacturing plants, and mines where they are vulnerable to both mechanical and respiratory injuries.

Another preconscription issue is the lack of education in many settings vulnerable to conflict. The opportunity for education is tied strongly to economic status and potential to avoid conscription (Betancourt et al., 2008b). The quality of education is tied strongly to economic status and potential to avoid conscription. In Mozambique, school drop-out students were recruited into armed forces with promises of better future (Boothby and Thomson, 2013).

Another major problem for children worldwide is abuse and neglect. Due to high rates of alcoholism, caregivers expose children to domestic violence and abuse. In addition to abuse, children suffer from neglect: because of endemic poverty, children are often unable to have their basic needs met. Moreover, in conflict-affected countries in Africa and Asia, there are few laws to protect children from child abuse and even fewer avenues for enforcement in most settings where children have been conscripted into armed groups (United Nations, 2005). Abuse and neglect creates vulnerability to recruitment. Child marriage is also child abuse. Child marriage was a common historical practice and still occurs in many settings where children have been used as combatants. Legacies of child marriage make girls vulnerable to being abducted as 'bush wives' for

Figure 1 Framework for life-history approach to risk factors for psychosocial problems among former child soldiers.

older men in military groups (McKay and Mazurana, 2004). In Nepal, fleeing from child marriage was a reason girls cited for joining armed groups (Kohrt et al., 2010b).

Gender discrimination is a profound factor that increases vulnerability to a range of psychosocial and mental health problems. Countries with a legacy of exploiting children as combatants score on the lower end of the Gender Development Index and Gender Empowerment Index. This pattern reflects the difference between women and men in the burden of labor; women are more poorly compensated than men. Lack of empowerment of girls may make them vulnerable to recruitment into armed groups as sexual slaves (Stark, 2006). In some settings, lack of opportunities for women may lead girls to join armed groups as a form of empowerment (Kohrt et al., 2010b).

(2) Experience of child soldiers during association with armed groups

The first issue to consider regarding association with armed groups is how a child was conscripted, as this may be a major determinant of subsequent well-being. Children become involved in armed groups through abduction, threats, pressure, manipulation and voluntary association. It is helpful to consider a division of risk factors for conscription into 'push factors' and 'pull factors' (Somasundaram, 2002). 'Push factors' are those factors that place an individual at risk of recruitment. Poor economic conditions, unemployment, and inability to meet basic needs in the community were reasons for joining. Children may join because of lack of opportunities in their communities and family problems. Girls may join to escape abusive marriages or may join prior to entering forced marriages. 'Pull factors' are aspects of the armed group that include both methods of recruitment, enticement, and promises made to children.

The most extreme 'pull factor' is abduction. Across the studies included in a recent systematic review (Betancourt et al., 2013a), abduction was the main mechanism by which children reported becoming involved with an armed group. Children in Mozambique were forcibly be made to join armed groups through kidnapping and abduction where they go through a series of cohesive and inhuman training and indoctrination before being integrated into armed forces; the children were kidnapped, separated gender-wise, and boys forcibly sent to armed forces while girls were made to serve the soldiers (Boothby and Thomson, 2013). In a study in Uganda among 330 sample child soldiers 99.7% were forcefully abducted (Klasen et al., 2013). However, in a Nepal study, nearly half of study participants joined without abduction (Kohrt et al., 2008), as did 18 out of 19 former child soldiers in the study from Sri Lanka (De Silva et al., 2001). In a study from El Salvador of 293 former child soldiers, 73.7% of study participants reported joining voluntarily and 3.4% reported

forced conscription (Santacruz and Arana, 2002). In these studies, ideological reasons for joining voluntarily included revenge, martyrdom, and 'desire to defend the motherland.' Other subjects reported joining out of fear of abduction.

Across the published studies of child soldiers, high levels of exposure to violence during association were reported. For example, several studies found that over 70% of child soldiers were severely beaten by armed forces, with similar rates reported by boys and girls (Amone-P'Olak, 2005; Amone-P'Olak et al., 2007; Bayer et al., 2007; Betancourt et al., 2011; Klasen et al., 2010; Kohrt et al., 2008). In an Ugandan study, more than half of the 330 sample child soldiers reported being directly involved in fighting, looting property, and injuring and killing other people (Klasen et al., 2013).

High levels of sexual abuse among girls were observed in samples from Sierra Leone (44%; Betancourt et al., 2011) and Uganda (30%; Klasen et al., 2010), as well as a mixed sample from Uganda and the DRC (57%; Bayer et al., 2007). Within the armed groups in Mozambique, girls were made to serve the commanders and soldiers as wives, servants and cargo carriers (Boothby and Thomson, 2013). Many girl child soldiers from African countries have reported sexual violence. This contrasts with Asian countries including Sri Lanka, Nepal, and the Philippines where intimate sexual or personal relationships without the female's consent and commander's approval were forbidden and would be punished. However, girls in the Philippines and Colombia have agreed to sexual relationships within groups if they knew it brought them some kind of benefits (Stevens, 2014). Boys were also victims of sexual abuse in these settings, although only Amone-P'Olak (2005) found higher rates of sexual abuse among boys (81 vs 72%) as compared to girls.

(3) Reintegration and postcombatant experience

While it might be assumed that removing a child from an armed group is the best approach, it does not assure psychosocial well-being. Increasingly, researchers have shown that the postcombatant reintegration experience is one of the main determinants of mental health, psychosocial well-being, educational outcomes, and livelihood (Annan et al., 2013).

Former child soldiers struggle with community stigma upon return home (Annan et al., 2009; Burman and McKay, 2007; Denov and Maclure, 2007; Denov, 2010; Shakya, 2010; Stark, 2006). For many adults, child soldiers are seen as threatening and morally corrupted (Boyden, 2003). In Sierra Leone stigma and perceived discrimination for being a former child soldier was significantly associated with worsening of posttraumatic stress symptoms over time (Betancourt et al., 2013b). In El Salvador, participants who experienced stigma scored higher on a psychological impact scale, as did youth who experienced feelings of disappointment upon return home (Santacruz and Arana, 2002). Longitudinal data from Sierra Leone indicated that stigma predicted higher levels of hostility/externalizing problems (such as behavioral problems characteristic of attention deficit disorder, oppositional defiant disorder, and conduct disorder) as well as deficits in prosocial behaviors over time, even after adjusting for war exposures (Betancourt et al., 2010a,c). In Uganda, abductees and non-abductees experienced similar levels of family and community rejection, while non-abductees were more likely to engage in prosocial behaviors such as participation in politics and community activities (Blattman, 2009).

Stigma may be connected with local idioms of distress associated with perpetration of violence. A study in Uganda found that the failure of reintegration was associated with widespread community resistance due to perceived unaccountability for the crimes committed and persecution from revenging spirits (*cen*) of those who have been killed (Akello et al., 2006). Community members perceived that minors committed war crimes and were free from punishment for their acts. Regarding *cen*, community members and child soldiers themselves perceived that child soldiers were being punished by spirits of persons they had killed. Therefore, the community avoided these child soldiers because of fear of their violent pasts and their affliction with spiritual afflictions related to their misdeeds.

Across settings, girls appear to suffer greater stigma and negative experiences during reintegration. There are estimated 120 000 female child soldiers worldwide and reintegration is particularly difficult for them (Stevens, 2014). Studies that stratified community acceptance by gender indicated differences in the ways families and communities treated returning boys compared to girls. In Sierra Leone, female former child soldiers experienced lower rates of acceptance as compared to their male counterparts (Betancourt et al., 2010b) and were commonly described as being akin to 'prostitutes' (Betancourt et al., 2008b). Girls in one study from Uganda also reported experiencing less community support (Annan et al., 2011). The trend continues even in Nepal where a study reported girl child soldiers experiencing gender-based community stigma related to local perceptions that their Hindu purity had been violated (Kohrt et al., 2010b). However, in a longitudinal study among child soldiers of Sierra Leone, girls demonstrated higher rates of improvement across the 4-year follow-up period (Betancourt et al., 2013b).

In addition to stigma and discrimination, postconflict factors such as educational and economic deprivation are associated with adverse outcomes (Betancourt et al., 2010a; Blattman and Annan, 2010; Wessells, 2009). Most studies have found that former child soldiers felt ill-equipped to contribute to their family economy upon return to civilian life (Annan et al., 2006; Boothby et al., 2006). In Uganda, access to resources have been identified as an important factor to help the child soldiers break away from their child soldier experiences, cope with bad feelings and mental health problems including nightmare, suicidal thoughts, and hallucination (Vindevogel et al., 2013a).

Reintegration means building positive relationships and coping with their intrusive feelings and stigma they face as former child soldiers (Boothby and Thomson, 2013). Family, community and peer support have been identified as important factors facilitating successful reintegration and psychosocial well-being. Family and community acceptance along with religious and spiritual cleansing ceremonies are important factors that facilitated successful social

reintegration of former child soldiers of Mozambique (Boothby and Thomson, 2013). In Sierra Leone, higher levels of family acceptance were linked to lower average levels of emotional distress among participants (Betancourt et al., 2010a,c). In this setting, caregiver–child open communication about traumatic experiences, and perpetration of violence in particular, might have a beneficial effect on positive adjustment outcomes (Borisova et al., 2013). Caregiver's adequate knowledge of direct violence was predictive of reported levels of depression among adolescents and of positive adjustment outcomes like prosocial attitudes, confidence, and self-agency. Supportive parenting was associated with better psychosocial adjustment in one study of Ugandan child soldiers (Derluyn et al., 2004). In Nepal, peer-related support was a strong predictor of psychosocial well-being: former child soldiers having strong peer support experienced increased hope and fewer post-traumatic stress disorder (PTSD) symptoms as well as reported better performance in daily functioning (Morley and Kohrt, 2013).

In Uganda, access to resources was linked with the child soldiers overcoming their current challenges, belonging to their returned environment, and a sense of being whom they wanted to be (Vindevogel et al., 2013a). Returning to and staying in school was associated with higher levels of confidence and prosocial behaviors among youth in a Sierra Leone study (Betancourt et al., 2010b).

Reintegration Programs, Traditional Healing, and Other Interventions

Facilitating successful reintegration of former child soldiers is one of the goals of the United Nations disarmament, demobilization, and reintegration (DDR) framework. Reintegration programs for child soldiers typically comprise economic and education support packages such as vocational training, apprenticeships, micro-finance loans, and formal or informal schooling. The intention of these programs is to prevent or mitigate the social, economic, and psychological sequelae of participation in an armed group. DDR programs should also involve caregivers and families in tangible ways to promote psychosocial well-being of reintegrated child soldiers (Borisova et al., 2013).

Potential protective factors for successful reintegration include community sensitization, cleansing rituals, transitional periods in interim care centers, religious support, psychosocial counseling, family mediation, and skills-based vocational training (Boothby, 2006; Kryger and Lindgren, 2011; Williamson, 2006). Attending school and training programs is considered critical in helping war-affected youth attaining a sense of normalcy and safety in their everyday lives while also increasing their future employment opportunities (Betancourt and Khan, 2008). In a study in Uganda, former child soldiers who were given the opportunity to continue their education scored lower on assessments of depression, compared to those who directly entered vocational training (Ovuga et al., 2008). Involvement of family is also crucial for effective interventions. In Sierra Leone inclusion of family-based elements resulted into greater impact of an intervention (Betancourt et al., 2013b).

A study of multisectorial reintegration assistance in Burundi found that former child soldiers who were socially integrated within communities had high work/employment rates, literacy rates above national average, and no differences in present functioning and mental health compared to never-recruited peers (Jordans et al., 2012). While coaching, on-the-job and vocational training and provision of material kits were associated with improved socioeconomic reintegration trajectories, a sense of satisfaction with received services is most strongly and recurrently associated with better outcomes. Community connection and a sense of future were also identified as protective factors among Colombian former child soldiers (Cortes and Buchanan, 2007). In the study, six Colombian child soldiers identified the factors that helped them overcome the effects of war. Feeling connected to the community and hope for the future were key factors. This was reflected in Nepal as well were having a sense of foreshortened future (i.e., thinking that one will not live as long as one's peers) was one of the strongest predictors of poor functioning in school, work, and social activities among children exposed to political violence (Kohrt et al., 2011).

Given the high burden of stigma and psychosocial problems among former child soldiers, using traditional healing rituals is an important trend in humanitarian interventions, particularly as combined with Western mental health services. Psychosocial practitioners, as well as anthropologists and other social scientists, have increasingly questioned the appropriateness and effectiveness of Western psychiatric therapies for survivors of mass violence, especially for children (Bracken and Petty, 1998; Psychosocial Working Group, 2003; Summerfield, 1998). In a Mozambique study, these traditional ceremonies played a vital role in rebuilding community trust and cohesion, as these ceremonies were believed to clean the child soldiers from their 'contaminated' atrocities of war (Boothby and Thomson, 2013).

In a study of former male child soldiers in Mozambique, traditional cleansing rituals were seen as promoting community acceptance (Boothby, 2006). In Sierra Leone, communities and families employed 'rituals of welcome' to incorporate returned girl soldiers into acceptable social positions (McKay and Mazurana, 2004). Honwana (2006) describes traditional healers in Angola conducting communal cleansing rituals for child soldiers to purify them of their exposure to killing. In Mozambique, traditional healers facilitated reintegrating ex-combatants by 'taking the war out of the people,' (Nordstrom, 1997: p. 146).

Reunification rituals or rituals of reintegration, however, may come at a cost to former child soldiers. For example, child soldiers are threatening to adults because they do not fall into socially expected roles of submission to adult authority (Boyden, 2003). Rituals may restore the expected socially submissive role of children, but this may represent a lost opportunity for children to gain a greater voice in social processes. The issue of girl soldiers exemplifies this challenge. Traditional rituals often reinforce gender discrimination by promoting the status of '(older) males' and "threaten the human security and well-being of women and girls" (Denov,

2007). Furthermore, Denov adds, "when assessing whether 'culture is always right', one cannot discount … the reality and implications of gendered exclusionary practices." Girl soldiers are particularly threatening for patriarchal societies. Therefore, adults use ritual to disempower girls and return them to socially acceptable subjugated roles. This raises the question of whether restorative rituals are the best practice for reintegration of child soldiers, particularly for girl soldiers. In Nepal, girls soldiers refused to participate in rituals during reintegration because they were perceived as a form of subjugation and antithetical to the reason they originally joined armed groups (Kohrt, 2015).

The peer-reviewed literature on former child soldiers includes few systematic studies of interventions to inform major policy decisions. In Côte d'Ivoire, 345 former child soldiers were enrolled in trauma-focused counseling supplemented by therapeutic workshops, literacy workshops, and resocialization exercises (Bissouma et al., 2010); in a pilot study in Liberia, 130 former child soldiers participated in a brief trauma-focused intervention (Gregory and Embrey, 2009). Two intervention trials were conducted in northern Uganda: Bolton and colleagues conducted a randomized controlled trial of Interpersonal Therapy with 314 war-affected youth (Betancourt et al., 2012; Bolton et al., 2007). Ertl et al. (2011) used three arms to compare Narrative Exposure Therapy, an academic catch-up and supportive counseling group, and a waitlist control condition among 85 former child soldiers, with significantly greater reduction of PTSD symptoms in the narrative group. In a randomized controlled trial in the Eastern DRC, Narrative Exposure Therapy for Forensic Offender Rehabilitation (FORNET) was offered to 15 ex-combatants with the goal of reducing traumatic stress and appetitive aggression compared to 'treatment as usual.' The results showed that FORNET helped reducing the severity of PTSD symptoms but not the levels of appetitive aggression (Hermenau et al., 2013). More research is needed to identify effective common elements in child soldier interventions as well as context specific elements for successful promotion of well-being.

Mental Health of Former Child Soldiers

It is difficult to make generalized conclusions about prevalence of mental health problems among former child soldiers, and it is especially difficult to isolate the effect of soldiering trauma on mental health among the range of other stressors that child soldiers experience such as poverty, lack of education, and stigma and discrimination. Variations in prevalence rates of mental health problems are in part attributable to problems in methodology, sampling, and instrumentation. There is notable heterogeneity in PTSD prevalence among studies with similar research designs. For example, in studies of formerly abducted youth in rehabilitation centers in northern Uganda, documented PTSD rates ranged from 99% (Amone-P'Olak, 2005; Amone-P'Olak et al., 2007) to 27% (Okello et al., 2007). Also in northern Uganda, one study investigating PTSD symptoms among 71 former child soldiers determined that PTSD symptoms were present in 97% of the sample (Derluyn et al., 2004).

It is now being suggested that research should extend beyond PTSD to tackle what is currently known about perpetration-induced trauma (Klasen et al., 2013). Another measure called Development Trauma Disorder (DTD) has been developed. In an Uganda study 80% of the sample former child soldiers met criteria for DTD while only 33% met criteria for PTSD, which supports that classic PTSD symptoms do not capture the overall trauma affect (Klasen et al., 2013).

Children may continue to suffer from psychological problems years after reintegration. In Uganda the effect of war-related trauma was seen even 6 years after the end of the war reflecting the adverse and long-term mental health effect on former child soldiers (Amone-P'Olak et al., 2014). Postwar environment are a key determinant of continued mental health problems in former child soldiers (Amone-P'Olak et al., 2014).

One question is whether child soldiering has a more negative impact on girls compared to boys. Female gender was a predictor of poorer mental health in studies in Sierra Leone (Betancourt et al., 2011) and Nepal (Kohrt et al., 2008). In the Sierra Leone research, more females scored within the clinical range for anxiety (80% girls vs 52% of boys) as well as depression (72% girls vs 55% of boys). When controlling for war exposures, female gender was significantly associated with lower levels of confidence and prosocial behaviors over time (Betancourt et al., 2010b, 2011). In the Nepal sample, there was a significant interaction between gender and child soldier status: girl soldiers had six times greater odds of having PTSD compared to those never conscripted, whereas boy soldiers had nearly three times greater odds of having PTSD compared with never-conscripted boys (Kohrt et al., 2008).

Comparing samples of children in the same conflict who were not conscripted in armed groups to child soldiers is an approach to identify the unique contribution of child soldiering on mental health. In studies with comparison groups, PTSD prevalence was greater among former child soldiers compared with never-conscripted children (Kohrt et al., 2008; MacMullin and Loughry, 2004; Okello et al., 2007; Vindevogel et al., 2013b). In Nepal, this distinction was maintained even after controlling for exposure to violence (Kohrt et al., 2008). By contrast, studies from northern Uganda found little difference in psychosocial distress levels between former child soldiers and comparison groups (Betancourt et al., 2013b).

Future Directions for Research and Intervention

With the growing knowledge about child soldiers, there are new directions in prevention and reintegration activities. Jordans and colleagues (Jordans et al., 2012) argue that successful reintegration is about the *equality* in opportunities, participation, well-being, and social functioning of former child soldiers compared to those of their never-conscripted peers. Reintegration also means building positive relationship in face of stigma they face as former child soldiers (Boothby and Thomson, 2013). Whether or not a former child soldier has found employment, is married, received education, or experiences few mental health problems are indicators of

long-term reintegration primarily vis-à-vis the average of the population at large or their peers.

There is a need to consider long-term development of mental health care services rather than services that attend to acute relief efforts. World regions affected by war and armed conflict often lack a standing and effective mental health care system, especially for children. There is a need to consider how the energy, human resources, and finances invested during the postconflict period can be extended to services that will last beyond the acute bolus of support. Amone-P'Olak et al. (2014) argues that policies and interventions to reduce long-term mental ill-health should address both postwar environment and mental health care as complementary. Strengthening the health systems in war-affected regions to respond to the mental health situation through both psychosocial interventions and mental health treatment should be prioritized (Amone-P'Olak et al., 2014). Moreover, in postconflict settings, mental health and psychosocial problems after war may be as related to chronic structural violence factors as to war-related exposures. Interventions should strongly consider chronic social problems as well as war trauma.

To prevent recruitment of child soldiers, interventions at the national level are needed to promote the inclusion of children's issues and voices. Through dialogue with policy makers, advocacy is needed for increased child protection to tackle abuses such as forced child marriage and child conscription in armed groups, as well as further capacity building of local institutions concerned with human rights protection, which currently often take place in a culture of impunity. Further initiatives are required whereby children's voices could be incorporated in planning, designing and monitoring, and evaluation of child protection programs. At the macro-social level, there also needs to be interventions to address the issues of poverty, ethnic discrimination, gender discrimination, protection of human rights, and decentralization of power.

At a more fundamental level, structural violence including poverty, inequality, and militarization are key issues. Policy and advocacy is needed to reduce the small arms trade that makes child soldiers more appealing, and to reduce the provision of large arms to militaries. Moreover, there should be continued international political pressure to encourage more representative inclusion of women, and ethnic minorities in governments in conflict-affected countries to assure that their needs are met during the rebuilding of society. International political pressure is needed to ensure a transitional justice process that allows for the involvement and participation of children and youth in political processes in postconflict societies. A clear mechanism for children to express their political rights, such as in the Truth and Reconciliation Bill, and citizenship is needed to supplant the system of child exploitation by political groups. International pressure and monitoring bodies, such as the 1612 U.N. Task Force (United Nations, 2005), can foster enactment of child-centered legislation and assure that political and legal processes meet international standards.

Child Soldiers as Victims and Actors: Lessons from Ethiopia

Tassé Abye, University of Nouakchott, Ksar, Nouakchott, Mauritania

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The international consensus achieved through a large campaign organized by humanitarian groups depicts children involved in armed conflict only as victims, an approach challenged by research-based and empirical studies. Consequently, divergent views on the sociological and/or political meaning of child soldiering have emerged recently. Humanitarian organizations have also tended to focus on child soldiers on the African continent. This article uses a child-centered perspective to demonstrate that child soldering may also result from political engagement.

Introduction

The Geneva Convention of 1949 defined the age of child soldiers as 15 years for child protection purposes; the 1977 protocols raised it to 18. The Cape Town principles accepted the definition in the 1977 Protocols and extended their scope. These principles suggest that a 'child soldier' is any child (boy or girl) less than 18 years who is part of any regular or irregular armed force or armed group involved in any capacity including cooks, porters, messengers, and anyone accompanying such groups, other than family members. It includes girls and boys recruited for forced sexual purposes and/or forced marriage. The definition does not refer only to a child who is carrying, or has carried, weapons. This definition is widely accepted and was endorsed by the United Nations General Assembly in 1989 through the Convention on the Rights of the Child (CRC). However, in 2002, the Optional Protocol of the CRC on Children's Involvement in Armed Conflict provided legal instruments that outlawed child soldiering. The international consensus gained through the humanitarian groups' campaign depicted children only as victims. This has been challenged by subsequent research. Consequently, divergent views on the sociological and/or political meaning of child soldiering have emerged during the past 20 years (Krijn and Richards, 1998; Hoffman, 2010; Brett and Specht, 2004). During this time, humanitarian organizations have also focused on child soldiers in the African continent. I examine these issues in this article, using original research based on Ethiopian experiences.

The Paris Principles of 2007 further developed and gave prominence to the 'victim approach' to child soldiering. Article 11 proposed that "children under 18 years of age who are or who have been unlawfully recruited or used by armed forces or groups and are accused of crimes against international law are considered primarily as victims of violations against international law and as alleged perpetrators."

That over 300 000 children are engaged in different conflicts across the globe is a dramatic international concern. Jezequel (2006: p. 1) identified the humanitarian focus on those living in the African continent. He states, "seven out of nine reports … by Human Rights Watch on the use of child soldiers in the last ten years, concern sub-Saharan African countries." The atrocities committed during the recent 'civil' wars in Sierra Leone, Somalia, Uganda, and different parts of Africa, contributed to shaping and framing the image of child soldiers as an African phenomenon. These child soldiers are described simultaneously as nonhuman, victims, perpetrators, killing machines, and pirates. Beah's (2007) personal experiences, other publications, and the international media have contributed to this image.

The devastating consequences of these different wars and the important roles children played in these armed conflicts, have contributed to this significant 'consensus' around the victim approach among humanitarian and governmental organizations. Academics approaching child soldiering from another perspective have found it a highly intimidating exercise. Shedding light upon or analyzing these issues from different angles has been interpreted as denial and insensitivity at best; at worst, a betrayal of the suffering of thousands of children from the consequences of inhuman wars. Moreover, when academics of African origin attempt to articulate child soldering in a fashion differing from the mainstream approach, it may be understood as merely defensive attitudes about their continent – compelling 'African' authors like me to avow that this is not our intention. Such research may be limited in scope to one country and there is no pretense of drawing a general conclusion from it.

Methodological Considerations

The argument I present in this article comes from a small research project aiming to understand the journey of those engaged in armed conflict in Ethiopia during the military regime (1974–91). Those study participants engaged in armed conflict during this specific period were part of an armed movement against a dictatorial government. Those siding with the military regime are not covered by this research.

This article is part of a larger research project of 8 years' duration on Ethiopian guerrilla movements. Among my sample for this publication are individuals who are 'happy' winners of the war against the military regime. Some hold political power in Ethiopia now; others have abandoned political life for other activities becoming professors, consultants, computer scientists, writers. I also interviewed former guerrilla fighters who have ended their struggle against the

military regime and live in other countries as migrants/refugees. I chose qualitative rather than quantitative research to explore the trajectories of former guerrilla fighters, and used snowball sampling to select the participants. Recently, I also had the opportunity to live in Ethiopia for 6 years. During this period, I observed former guerrilla fighters in various situations and enriched my understanding.

I also attended several gatherings of former guerrilla fighters who remained at home and comrades returning to Ethiopia from their migration journeys. These gatherings would often occur in the house of a former combatant and provided important opportunities for ethnographic observations. These events became 'celebrations' that began during late afternoon on weekends and lasted until late night. The learning provided was amazing. The former fighters turned migrants and those who never left would scrutinize, discuss, celebrate, mock, and tease each other, thereby rehearsing their previous collective past. There were moments where one of their roles during a specific operation was recalled and I observed how these discussions clarified questions that had been obscure for some participants. Combatants who had lost their lives during the war were remembered. I used these moments to learn about individual roles and positions before and during guerrilla life, and to contact individuals for further in-depth interviews. The informality of the discussions and their settings gave me a tremendous opportunity to clarify many questions that would have been difficult to grasp in formal individual interviews.

As researcher, I also observed two congresses of the Amhara National Democratic Movement (ANDM), attended by over a 1000 former guerrilla fighters. The congresses provided a huge opportunity to observe discussions among former guerrilla fighters currently living in different socio-economic conditions. During my time at Addis Ababa University, I could also work closely with former guerrilla fighters who had become members of academia.

I conducted 54 in-depth interviews with former guerrilla fighters (37 men and 17 women). However, the findings for this article relate chiefly to fighters aged less than 18 when they joined the armed struggle. This category encompassed 30 individuals (21 men and 9 women); each was interviewed for 2 h. They varied in age from 11 to 17 years. With five ex-rebels, I held lengthy, multiple interviews that lasted around 3 consecutive days. These usually took the form of a 'retreat.' The names (fictitious) I gave to these former fighters are Tarikuwa, Tesfayé, Kumeta, Tesfa, and Tadios. I thank them for the substantial time they gave to share their knowledge.

Women guerrilla fighters constituted around 30% of interviewees. Although limited in number, my research gives them voice. A major limitation of this study is the exclusion of former guerrilla fighters who today live as peasants. They represent the largest and most important group among Ethiopia's former guerrilla fighters. Their inclusion could bring another level of understanding to modes of engagement and their lives within the guerrilla movement and afterwards.

Thus, this research provides a limited and tentative understanding of the trajectories of a small number of Ethiopian former child/youth guerrilla fighters, without pretension of having a total understanding of the entire domain. However, it contributes to enlarging an area of research that has been insufficiently studied by social scientists in Ethiopia and beyond.

Context for Engagement

A number of guerrilla movements were formed during Ethiopia's Imperial reign. However, the February 1974 revolution became a turning point in contemporary Ethiopian history because this led to former combatants becoming part of the country's political elite and impacting daily life. This revolution 'surprised' political observers and activists. Started with a political slogan, *Yale Meneme Deme* (without a drop of blood), it became one of the bloodiest revolutions during the late twentieth century. In the absence of a strong, identifiable, and organized political party, a military group known as the *DERG*, who had neither a clear political agenda nor an articulated strategy, seized power.

The Ethiopian Left was recruited disproportionally among university and high school students. While the student movement's level of engagement prior to the revolution had been relatively high, its intensity was not comparable to the revolutionary momentum. The rapidity and magnitude of political involvement had no precedence in the country's history. While *a priori*, nothing had prepared them for a high commitment to politics, they acted as if they were ready and waiting for the revolution to come. The notion of *Zeitgeist* (spirit of the time) used by Gérard Chaliand (2008: p. 35) could explain their rush to engagement?

The relative ease with which the Imperial regime was ousted could have created in the perception and analyses of emergent political groups and their supporters, an illusion that a popular force could bring down any government if the will existed. Kiflu Tadesse, a leading Central Committee member of EPRP, ensured that 5 months after the beginning of the revolution, "a provisional youth league committee was formed with an assignment to set up the structure of the League" (Tadesse, 1998: p. xxix).

The politicization of the country's youth and its engagement in political organizations was reinforced through the *Zemecha* (Campaign). On 24 December 1974, the military government formulated a policy demanding that all university and high school students and teachers participate in a campaign that contributed to the betterment of peasant life. The military regime sent young people, aged 15 to 16 years and beyond, to the countryside to fragment and limit the emergence of an opposition, because it feared social upheaval. The closure of high schools and institutions of tertiary education had exactly the opposite effect. The engagement of young people in political activism can largely be attributed to ERP mobilization work during the *Zemecha*. About two-thirds of the interviewees trace their political engagement to their involvement in the *Zemecha*.

During this period of Ethiopian history, membership and allegiance to, or sympathy with, political movements had become a significant practice even for those aged 13 to 14 years. Organizing dance parties and listening to American music on the radio program 'Listeners Choice' had been a 'must' for large groups of young people living in cities, but they became unfashionable after the revolution. Young urban youths chose to participate in political meetings, workshops, read the works of Marx, Engels, Lenin, Stalin, and Mao, and actively engaged in

clandestine political Party Cells. Compared to young people, the number of 'adults' participating in underground political movements was smaller. Spending the night close to a library to be among the first to access Marxist books that arrived from abroad was comparable to today's reaction to the launch of a new Harry Potter book or new version of a playstation in major European or American cities.

The transformation of Ethiopian youth was radical. Young people in cities, especially the capital but also in the different provinces, discovered new role models through TV, radio programs, films, books, and pamphlets distributed by political groups such as *Democracia*, the EPRP official publication. Watching Chinese films like 'From Victory to Victory' had become an extremely popular activity.

Activities such as massive participation in demonstrations against the regime, delivering Party and Youth League pamphlets clandestinely, tagging cities with revolutionary and antigovernment slogans under the cover of night, placed the regime under high levels of stress. In response to the large-scale mobilization of young people, exactly 2 years after assuming power, the military government framed a new policy and announced the *Red Terror* on 11 September 1976. The military regime acted with extreme and widespread brutality. The military junta authorized government supporters, the army, police, and kebele militia to kill, torture, and imprison whomever they suspected. The government published multiple decrees limiting if not suppressing the freedom to write, demonstrate, organize, and even to think. Granted the right to kill, government supporters locked the cities and implemented the 'search and destroy' campaign.

During the May Day demonstration of 1977, according to Ottaway and Ottaway (1977: p. 147), "Hundreds were arrested, taken to three different sites on the outskirts of Addis Ababa, and executed *en masse*. Scores of others were gunned down in the streets by the Derg's 'permanent secretaries', the jeeps mounted with machine guns constantly patrolling the streets of Addis Ababa. The death toll may have been as high as 1000 for that single day." Christopher Andrew and Vzsili Mitrokhin (2005: p. 457) citing Amnesty International estimates, inform us that during the first days of the *Red Terror*, "the death toll could be as high as 500 000." The army, not satisfied with liquidating the country's youth, demanded that parents paid for the bullets that had killed their children if they wished to bury them.

That the EPRP quickly gained substantial support not only from young people but also from the few industrial workers and some members of the National Defense Forces (including members of the DERG) may have created over-confidence among the EPRP's leadership. They may have believed that they could take political power from the military junta without a long guerrilla war. A number of EPRP publications of that time suggested that the military government was very weak, without any social base to sustain its power. The military junta '*stands on pins and needles*' was the EPRP's credo.

The overall situation country-wide did not provide other alternatives for Ethiopia's young people. The slightest difference with the regime was immediately sanctioned by imprisonment, torture, or killing. While leaving the country and seeking refuge in neighboring countries had become the solution for many, others decided to organize in armed struggle against the regime.

"Almost unnoticed in these chaotic conditions, in 1975 a small group of university students calling themselves the Tigray People's Liberation Front (TPLF) launched an armed struggle for national autonomy for the northern province of Tigray" (Young, 1998: p. 36). Unlike the EPRP, the TPLF started rural armed struggle as the main form of engagement. Alongside collective struggle, some Tigrayan students and activists had been organized around their regional identities. Within the Left movement in Ethiopia, the issue of ethnicity has been an important organizing factor and remains central even today. Left activist Wallelign Mekonnen's (1969) famous article, *On the Question of Nationalities in Ethiopia*, became a landmark.

The Ethiopian People's Democratic Movement (EPDM) (later renamed Amhara National Democratic Movement) emerged in 1980, as a result of the 'partial' disintegration of EPRP/EPRA, which did not last long as the major political party attracting and fascinating Ethiopian youth. Five years after the official launching of the party and the formation of its armed wing, the EPRP/EPRA was dismantled.

Political Activism – A Prelude to Armed Struggle

Contrary to the image the international media broadcast of young people captured and forced to fight in wars that they did not understand, those interviewed for this research had made a conscious decision to participate in armed struggle. Among these were two types of participants: those who had been activists prior to becoming guerrilla fighters (24 out of 30); and those with little experience of militancy before joining the armed struggle (6 out of 30). Additionally, age when joining the armed struggle, place of residence, and level of education distinguish these two groups. Most of those who joined the guerrilla movement with earlier activist experience came from the cities, particularly Addis Ababa, Gondar, Mekele, and Axum; their average age was 15 years; only five were aged 17 years. Among the six respondents who joined the armed struggle without prior political experience, all but one were from rural areas and lived close to military bases of guerrilla organizations. The average age for this group was 15 years.

Many activists, particularly those who joined the armed wing of EPRP/EPRA, decided to engage in the rural armed struggle as a means of escaping imprisonment by the military regime. Tedros, who occupied ministerial positions for close to 20 years after the victory of Ethiopian People Revolutionary Democratic Forces (EPRDF), was a young EPRP activist studying at high school in Addis Ababa. He explained his decision to join the guerrilla movement as:

> I knew from other comrades that I was identified by the regime security. I had to stay underground in Addis for several weeks before the party arranged my escape to *Assimba*, Tigray and join the EPRA-…It was not safe to stay in Addis either for me or the party. Tedros said he was identified as *Tebeleché neber* (translated as 'I was eaten'). Moreover, *tebeleché, tebelah*' in some regions referred to the evil eye (Buda in Amharique), bringing an association between the military regime's security services' evil eye (*buda*) with another translation 'I was cheated, or I lost'.

Tadios, minister in the current government, joined the armed struggle when he was 17 years old. A member of the EPRP at 15, he worked against the military regime's objective of mass conscription of peasants from his region. His decision to join the armed struggle resulted from difficulties in remaining in the city. Exposed to some form of political life while studying at high school, he was recruited into EPRP during the *Zemecha*:

> While we were in the *Zemecha*, we heard that we were going to be killed by the security [forces] of the government. We left the *Zemecha* camp and two months later, I was asked to leave for the EPRA through a Party channel. At that time, *Belessa* was identified as the main area for the armed struggle in Gondar; because of my knowledge of that region, I and two others were sent by the Party to the EPRA.

Hailu, born into a family with a long tradition in the priesthood, a traditional career for the country's educated elite, became engaged in political activities during junior high school. Here, Hailu's major activity besides formal education was political action. The level of political activities in junior- and senior-high school in Ethiopia's cities during that period is difficult for outsiders to imagine. The kids at the school were divided into two major groups: those considered Left-wing and those supporting Haile Selassié's regime. Hailu recalled, "We had our red hats to distinguish us from those reactionaries … at one time there were no red hats left in town, they had been all sold out." A Left-winger at age 14 years, he was elected as member of the student association in high school. "It is through a university student coming back for vacation and others arriving for university service that I started to become involved in larger political activities prior to the revolution." Arrested by the Imperial security forces for being a political activist before reaching 18 years, he joined the EPRP a few days after Tadios.

The notorious *Shaleka* (Commander) Melaku governed the region where Tadios and Hailu lived. As Governor of the Gondar region, *Shaleka* Melaku was known for implementing the most monstrous program of mass killing and torture. Under *Shaleka* Melaku's leadership, thousands of young men, children, and women were killed, tortured, and jailed for belonging to the target age group: being young. Hailu, as many others who lived in the city, recited a popular lamentation of a woman whose son had been sent to Gondar prison: 'Shaleka Melaku, Ye Igzeir Tanash Wondem, Ye Zarein Marelign Ke ingdih Alwoldem' (translation: 'Commander Melaku, God's youngest brother, forgive my son for today. I promise never to give birth').

Given such oppression, Tariku recalled that sending activists to join the guerrilla movement was a last resort. Many had to stay and work underground in different Party structures for months and only when it became unbearable were they sent to join the rural armed struggle. Living underground in cities like Addis Ababa or Gondar was made extremely difficult after the government started house-by-house searches for EPRP members or anyone considered a potential activist. The numbers of those caught, imprisoned, and killed was countless. According to Kiflu Tadesse (1998), after 3 years of existence (1974–77), the EPRP/EPRA in Tigray, for example, counted only 200 fighters. Starting in 1976/1977, the *Derg* had launched a massive offensive against the EPRP in cities and killed many activists. However, by the end of 1977, the number of fighters in the ERPA in Tigray rose to over 1000 (Tadesse, 1998: pp. 365–373).

Also, the TNO/TPLF was preparing for rural armed struggle. Tito, a former top-ranking military officer, now a consultant on security and peace, recalls, "My engagement into political activities dated from my high school days. Having Zeru Keshen as a teacher (Zeru Keshen, was a leading University student activist and later a member of the Central Committee of the EPRP) was instrumental for me. His discussions pushed us to reflect on the situation of the country and made us think about and analyze it. But I think that it was during the *Zemecha* that I totally embraced the revolutionary struggle."

Berhane had the same experience as Tito: "After hesitating whether to join the TPLF or EPRP, I joined the TPLF directly from the *Zemecha* at 17 and never went back to my parent's home." Tesfayé, born to a poor peasant family, was in high school when he became interested in politics. He recalls that his political engagement was highly influenced by the teachers he met, a professor of Sri Lankan origin, and university service students like Estiphanos Seyoum.

Seifu, a 10th grade student, discovered politics during the *Zemecha*. He performed a wide range of political, administrative, and economic activities on behalf of the current ruling party until 2003 when he resigned from government and political activities to join the higher education system. He holds a Masters degree from a major American university and is currently enrolled for a PhD there. Explaining why he joined the armed struggle, he said:

> It was during the *Zemecha* that I discovered politics as did many students at that time, I was about 16 years old when I decided to join the armed struggle. The government was then engaged in a systematic harassment of the young generation in the entire country but more importantly in Tigray.

Like many others, Tafesse, was in high school in 1974 and traces his political engagement to the *Zemecha*.

> We were, 120 students who had been sent to the Benichangol region. The *Zemecha* students were organized in sub-groups of seven or eight, I was placed in a group of four strong university students who were articulate about the revolution and inspired us. Back in Addis, I joined the EPRP Youth League. That is how I started politics.

The different interviews and discussions held during this research revealed that those who joined guerrilla movements in the early stages of the struggle had some exposure to the Left-wing literature available then. Four of the nine women interviewed in this study, had become politically active through the *Zemecha*. Most were junior or senior high school students.

Although there is evidence of young men and women joining the armed struggle through some form of collective 'obligation,' (some villagers were persuaded to contribute by encouraging children to join the armed struggle in the combatant cadres), those interviewed stated clearly that they joined the armed struggle on a voluntary basis, thus

contradicting the commonly accepted assumption that they ended up in armies or armed opposition groups because they were either forced to join or because they lacked other options. Despite not being representative, respondents under the age of 18 indicated their determination to join the armed struggle. In Ethiopian society, *Jegnenet* (bravery) has structured the collective psyche. Ethiopian revolutionaries have used (and sometimes abused) traditional songs that celebrated individual engagement in performing acts of bravery, for mobilization and recruitment: 'Ye feri inate atechenki, lejish koura new nefsun tebaki, kezaf lay hono were teyaki. Ye Jegna inate tateki begemed, lejishin amora inji aykebrewem Balchaede.' (Translation: 'Mother of a chicken-hearted son, have no fear, your son is as wise as a raven, and will only gather information sheltered on the tree (sits idle while others sacrifice is implicit). Mother of a hero be brave and fasten your belt, unlike others, your son will die fighting and not be buried by his relatives (as a coward is implicit).')

Not a single interviewee mentioned that he or she had been forced or abducted, as observed by scholars of fighting forces in other conflicts. That the individuals I interviewed had been 'politically active' prior to their guerrilla engagement partly explains this situation. Moreover, for those living in neighborhoods near guerrilla military bases, their proximity to and contact with guerrilla fighters who originated from the large cities of Ethiopia, represented some form of access to 'modernity' and sophistication to which they aspired. Some may have considered joining the guerrilla movement as a 'rite of passage' to modern life. Toruwa, a member of the national parliament, said when interviewed, that he was the youngest in a family of five children and the only one to access education. Toruwa was in grade five and aged 13 years when she joined the armed movement. She said:

> I decided to join the armed struggle. The military base of the EPRP was not far from my village. These young men and women's commitment and discipline that I observed each time they passed our village impressed me. When I arrived in their military base, they did not know what to do with me. They discussed this for hours among themselves and were upset with those who allowed me, a kid, to join. Finally, they accepted me in the armed structures.

During several discussions held with members of the EPDM about their different wars, most praised Toruwa's courage. For many peasants in the countryside, Toruwa's unit was known to have been among the best fighters and was feared by many. That she was one of the few women occupying the position of commander played an important role in building her reputation.

While writing this article, Kumeta has just finished his PhD in a European university and returned to Ethiopia to teach and do research. Joining the guerilla movement at age 11, he was the youngest interviewee to do so:

> My uncle was a political activist and lived with us at my parents' home. He often explained the struggle to me. I had finished 6th grade…and really wanted to join the guerrilla fighters. I had tried twice to join the TPLF. Both times, the Front refused to enroll me arguing that I was too young. At my third approach, they finally accepted me. This time they were convinced that I would not go back. Somehow, I think that my insistence at remaining amused them.

Kumeta performed tasks ranging from radio operator to message conveyor for over 2 years before being engaged in the combatant forces.

Lungo, today in charge of an important national institution, recently gained a Masters degree from a well-known university in the United States. He joined the EPDM at age 16 years. Born into a small shopkeeper's family, he excelled at this trade when very young, "I use to go from one village to another to sell fabrics. Our area was a frequent passageway for the guerrillas. We really liked the way they were disciplined, the way they carried weapons, the way they walked.… At that time the Military regime's MIG fighter planes had already bombarded my village three times. When passing through our village, the guerrilla fighters had created structures for young people to have discussions with them … That is how some friends and I decided to join the guerrilla movement."

Conclusion

My interviews demonstrate that joining the armed struggle often resulted from prior political engagement. Beyond the national context of high repression, the revolutionary model for initiating change was highly valued by young generations in Ethiopia and other countries during the 1970s.

For Ethiopia, the *foco* (Mobile Strategic Force), a nucleus of a 'people's army,' to use Régis Debray's (1967: p. 24) term, was begun by university and high school students. Ethiopian armed struggle leaders, moved rapidly and deeply toward guerrilla organization and tactics, inspired by Maoism as well as Chinese and Vietnamese Irregular War theorists. The majority of combatants in Ethiopian guerrilla groups were drawn from the Ethiopian peasantry even though the instigators had been recruited primarily from the educated elite.

Most of those interviewed for this research possess important academic qualifications in their respective domains of study. They often mention their excellent academic standing in high school and at university. Statements about their academic performances are often followed by implicit comparisons to others in their age group. In evidencing academic achievements, former guerrilla fighters systematically indicated their young age (16–17 years) when joining university. It is as if these respondents wanted to ensure that the researcher understood that they made a conscious decision to become politically active and to sacrifice the possibilities for individual professional or social success that lay wide open to them.

Convinced that their socialist concepts could build a democratic system, these young university and high school students waged armed struggle to oppose the military regime that had usurped political power in their country and to liberate their people. These militants' characteristics do not correspond to those Ibrahim Abdullah and Patrick Muana (1998: p. 179) identified for the majority of those in the Revolutionary United Front of Sierra Leone, namely 'Lumpens, school drop-outs, young unemployed, illicit diamond miners

locally referred as *san–san boys*, drifters, hooligans, drug addicts and thieves.' The modalities of engagement, their social aspirations for Ethiopia and its population, their ambitions for the future, and indeed the lives of the young Ethiopian guerrilla fighters that I interviewed, had different motives and objectives from those in Sierra Leone.

Abstract

Research pioneered by Peter L. Benson, of Search Institute, has enhanced the study of developmental assets and thriving among youth. Thriving occurs when the strengths of youth are aligned with ecological developmental assets. Findings from the 4-H Study of Positive Youth Development (PYD) indicate that when individual and ecological assets are integrated, thriving occurs. We discuss contributions of Search Institute to the study of thriving, as well as findings from tests of the model of PYD by Lerner and Lerner.

In Peter Benson's last published work on the concept of developmental assets, an idea that he introduced into the developmental literature in 1990, Benson and his colleagues (Benson et al., 2011, p. 198) noted that:

> The framework of developmental assets, first posited in 1990 (Benson, 1990) and refined in 1995 (Benson, 1997, 2006), was explicitly designed to provide greater attention to the positive developmental nutrients young people need for successful development, not simply to avoid high-risk behaviors, and to accent the role that community plays in adolescent well-being…[t]he framework establishes a set of developmental experiences and supports hypothesized to have importance for all young people during the second decade of life. Recent work is taking a broader life span perspective, positing that developmental assets reflect developmental processes that have age-related parallels in infancy, childhood, and young adulthood.

This growing use of the concept of developmental assets occurred as a consequence of the importance of this concept within a broader model of youth development termed the positive youth development (PYD) perspective. We review the PYD perspective, and place special emphasis on the envisioned role of developmental assets in thriving among diverse youth. In turn, we summarize research examining the role of developmental assets in the promotion of PYD. Finally, we discuss implications of this research for evidence-based programs aimed at enhancing developmental assets for youth.

The PYD Model

The goal of developmental science is to describe, explain, and optimize intraindividual change and interindividual differences in intraindividual change across the life span (Baltes et al., 1977). Scholarship within this field is framed by relational developmental systems theoretical models (Overton, 2013; Overton and Mueller, 2012). According to these models, human development is shaped by the mutually influential relations between the developing individual and the multiple levels of his or her dynamic context. These bidirectional relations may be represented as individual ↔ context relations. These relations regulate the course of development. When these 'developmental regulations' are mutually beneficial to both the person and his or her ecology, they may be termed adaptive developmental regulations (Brandtstädter, 2006).

Examples of relational developmental systems theoretical models include Bronfenbrenner's bioecological theory (e.g., Bronfenbrenner and Morris, 2006), action theory models of intentional, goal-directed behaviors (e.g., Brandtstädter, 2006), Elder's (1998) life course theory, Magnusson's (e.g., Magnusson and Stattin, 2006) holistic person–context interaction theory, and the Ford and Lerner (1992) and the Gottlieb (1998) developmental systems formulations.

History, or temporality, is part of the ecology of human development that is integrated with the individual through developmental regulations. As such, there is always change and, as well, at least some potential for systematic change (i.e., for plasticity) across the life span (Baltes et al., 2006; Lerner, 1984). This potential for change represents a fundamental strength of human development. Of course, plasticity is never absolute; it is relative in the sense that development involves an integration of change-promoting and change-constraining processes and, as well, the integration of gains and losses in structure and function across the life span (Baltes et al., 2006). In addition, change for the better or worse can characterize any individual's developmental trajectory. Nevertheless, a key assumption of relational developmental systems theories – and, as we will note, of the use of these theories to understand both adolescent development in general and to frame the PYD conception of developmental processes more specifically – is that the developmental system is sufficiently diverse and complex such that there are a multitude of ways for researchers and practitioners to facilitate mutually beneficial individual ↔ context relations that may enhance the probability of change for the better and of promoting more positive outcomes of human development (J. Lerner et al., 2013).

During adolescence, there are several individual and contextual changes that are manifested in the developmental system. Changes in the prefrontal cortex, increases in the interconnectivity among brain regions, and increases in dopamine levels provide both vulnerabilities to risk and opportunities for growth in cognitive control and self-regulation (Steinberg, 2010). At the same time, youth may experience contextual

changes, such as changing schools (e.g., Eccles, 2004) and the increased relevance of peer pressure for risk-taking (e.g., Brown and Larson, 2009). Moreover, during adolescence, the individual has the cognitive, behavioral, and social skills to contribute actively, and often effectively, to his or her own development (Lerner, 1982). Accordingly, adolescence is an ideal developmental period for studying the relative plasticity of human development and for exploring how, through matching individual strengths with ecological developmental assets within the developmental system, positive development may be promoted.

The Study of Adolescence within the Relational Developmental System

The adolescent period is characterized by multiple dimensions of change involving levels of organization ranging from the physical and physiological, through the cognitive, emotional, and behavioral, and to the social, relational, and institutional. As previously mentioned, relative plasticity represents a fundamental strength of the adolescent period (Lerner, 2005, 2009) in that it reflects the potential for systematic changes that may result in more positive functioning. If adaptive developmental regulations emerge or can be fostered between the plastic, developing young person and features of his or her context (e.g., ecological assets linked to the structure and function of his or her family, school, peer group, and community), then the potential for thriving in youth may exist across the adolescent decade.

Indeed, predicated on relational developmental systems theories, the links among plasticity, adaptive developmental regulations, and positive development suggest that all young people have strengths that may be capitalized on to promote *thriving* (i.e., exemplary positive development; Benson et al., 2011) when integrated with developmental assets across the adolescent years. One example of the emerging strengths of adolescents is their ability to intentionally influence adaptive developmental regulations with their context (Gestsdóttir and Lerner, 2008). For instance, such intentional self-regulation may involve selecting positive goals that reflect important life purposes, using cognitive and behavioral skills (such as executive functioning or resource [asset] recruitment), to optimize the likelihood of achieving one's goals and, when goals are blocked, possessing the capacity to adjust or compensate effectively (Baltes and Baltes, 1990; Freund and Baltes, 2002).

When viewed from the perspective of relational developmental systems theories, young people represent 'resources to be developed' as opposed to the historical deficit view that young people are 'problems to be managed' (e.g., Roth and Brooks-Gunn, 2003). This strength-based view of adolescents has been used to study PYD within the United States (e.g., J. Lerner et al., 2013) and internationally (e.g., Gestsdóttir and Lerner, 2007; Silbereisen and Lerner, 2007). As previously noted, this research has been framed at a 'meta-level' by the ideas of individual ↔ context relations within relational developmental systems models. In addition, the research has been influenced by interest in the characteristics of PYD that emerge from this relational process, by the individual and ecological bases of these characteristics, and by interest in outcomes of the PYD process (e.g., youth community contribution or active and engaged citizenship) (e.g., Zaff et al., 2010).

There are several instantiations of this theoretical approach. Benson and his colleagues (e.g., 2006, 2011) formulated one such illustration and, in turn, Lerner and Lerner (e.g., J. Lerner et al., 2012) have expanded on Benson's model to propose a related conception of positive development (see J. Lerner et al., 2012 for a fuller description of other models, e.g., those of Damon, 2008; Eccles, 2004; Hamilton and Hamilton, 2005; Larson, 2000; Masten, 2001; Spencer, 2006). We first discuss the Benson developmental assets model, followed by the Lerner and Lerner model.

Peter Benson and Search Institute, and the Study of Developmental Assets

The work of Peter Benson and his colleagues at Search Institute (e.g., Benson, 2008; Benson et al., 2011) has been integral in providing the vocabulary for, and vision of, the strengths of young people and the communities in which they live, through the study of 'developmental assets.' Benson and his colleagues describe 'internal' or individual assets (i.e., 'skills, competencies, and values' of a young person) that are grouped into four categories: (1) commitment to learning; (2) positive values; (3) social competencies; and (4) positive identity (Benson et al., 2011). These individual assets represent the talents, energies, strengths, constructive interests, and 'sparks' that every young person possesses (Benson, 2008). When these individual strengths are aligned with 'external' or ecological assets (i.e., other individuals, community-level networks, institutions), thriving occurs. The ecological assets are conceived of as 'environmental, contextual, and relational features of socializing systems' and are organized into four categories: (1) support; (2) empowerment; (3) boundaries and expectations; and (4) constructive use of time (e.g., Benson et al., 2011).

Benson and his colleagues found these assets to be predictive of seven behavioral indicators of *thriving* including (1) school success; (2) leadership; (3) helping others; (4) maintenance of physical health; (5) delay of gratification; (6) valuing diversity; and (7) overcoming adversity (see Benson et al., 2011 for a review). For example, when internal assets (such as achievement motivation and school engagement) are combined with external assets (such as time spent in youth programs), school success was significantly predicted for six different racial/ethnic groups of 6th–12th grade students. In addition, higher levels of assets have been related to other positive developmental outcomes, including better physical health, lower levels of risk behaviors, and resilience (Scales et al., 2003).

Benson and colleagues have emphasized the importance of exploring potential practical applications of research on developmental assets by highlighting the role of communities in fostering well-being and positive development among young people. During the last two decades, research from Search Institute has helped communities to develop strategic goals and program initiatives for promoting PYD. Today, more than 300 communities across the country have incorporated Search Institute's asset-building framework into their efforts to foster positive and healthy functioning among youth.

In sum, the work of Benson and his colleagues has focused on research and applications aimed at connecting the strengths of youth with the assets of communities and building upon them to promote positive development. Current research by Search Institute seeks to extend the developmental assets approach to diverse youth in American and international contexts.

Richard M. Lerner, Jacqueline V. Lerner, and Colleagues, and the Study of Individual ↔ Context Relational Processes and PYD

Lerner, Lerner, and colleagues (e.g., J. Lerner et al., 2013) conceptualize PYD by drawing on the mutually influential individual ↔ context relations that underlie the PYD process. Their model has been tested longitudinally in the 4-H Study of PYD (e.g., Lerner et al., 2005, 2011), which seeks to identify the individual and ecological relations that may promote thriving and prevent risk or problem behaviors. Within the study, thriving is perceived as the growth of attributes that mark a flourishing, healthy young person (e.g., the characteristics termed the 'Five Cs' of PYD – competence, confidence, character, connection, and caring) (Eccles and Gootman, 2002; Lerner et al., 2005; Roth and Brooks-Gunn, 2003).

A key hypothesis tested in the 4-H Study is that, if: (1) the strengths of youth (e.g., a young person's cognitive, emotional, and behavioral engagement with the school context or possession of intentional self-regulation skills such as selection, optimization, and compensation (SOC)); can (2) be aligned with ecological developmental assets (e.g., other individuals, institutions, social networks); then (3) young people's healthy development may be optimized (J. Lerner et al., 2013). In addition, since positive development is characterized by adaptive and mutually beneficial relations between the developing young person and his or her environment, then thriving youth positively shape and are shaped by their environment and, as such, should be positively engaged with and act to enhance their world. In addition, they should be less likely to engage in risk/problem behaviors. **Figure 1** presents an illustration of the Lerner and Lerner conception of the PYD developmental process.

The figure illustrates that adaptive developmental regulations and their positive and problematic *sequelae* exist within the broader ecology of human development. This ecology includes history and culture and, thus, introduces change at all levels of organization within the developmental system (Bronfenbrenner and Morris, 2006; Elder, 1998).

Empirical Support for the Five Cs Model of PYD

As indicated earlier, in order to test the ideas presented in **Figure 1**, researchers at the Institute for Applied Research in Youth Development at Tufts University launched the 4-H Study of PYD in the fall of 2002. The 4-H Study of PYD is a longitudinal investigation supported by a grant from the National 4-H Council and the Altria Corporation. Data were collected annually from youth in Grades 5 through 12 in order to study youth in their actual environments, where youth and their parents, rather than research investigators, make decisions about how they spend their time. Full details of the methodology of the 4-H Study have been presented in numerous empirical publications (e.g., Lerner et al., 2005, 2011). Findings of the 4-H Study have provided empirical support for several key ideas within the Lerner and Lerner PYD model, including the antecedents of PYD as they may exist in the relations between youth strengths and ecological assets.

From the relational developmental systems PYD perspective, all young people have strengths that may be capitalized on to promote thriving across the adolescent years. One example of the emerging strengths of adolescents is their ability to contribute intentionally and actively to the adaptive developmental regulations with their context; for instance, as indexed through the use of SOC behaviors (Freund and Baltes, 2002; Gestsdóttir and Lerner, 2007, 2008). Other instances of strengths include specific self-regulations in key contexts of adolescents, as demonstrated through school engagement (Li, 2011) and future-oriented beliefs and emotional structures (Schmid et al., 2011a,b). For example, having a hopeful future orientation may help to activate adolescents' self-regulatory skills, even in the face of challenges.

The Lerner and Lerner PYD model specifies that the strengths of youth are linked to PYD in the context of ecological assets. The 4-H Study assessed the role of these assets in the PYD process depicted in **Figure 1**. The relations among observed ecological assets in the families, schools, and neighborhoods of youth with positive and negative developmental outcomes were assessed among 5th-grade youth from the 4-H Study (Theokas and Lerner, 2006). Ecological asset indicators were categorized into four categories: (1) human; (2) physical or institutional; (3) collective activity; and (4) accessibility, and were measured equivalently across the three contexts. Different dimensions of the family, school, and neighborhood settings had the most comprehensive impact on developmental outcomes, specifically on collective activity in the family, accessibility in school, and human resources in the neighborhood. However, in all settings, assets associated with individuals were the most potent predictors of PYD. Family assets were most important in the lives of youth; as such, one of the strongest predictors of PYD was eating dinner together as a family.

Subsequent analyses of the youth from Theokas and Lerner's work (2006) indicated that neighborhood dimensions interact with adolescent extracurricular activity involvement to predict PYD, depressive symptoms, and risk behaviors (Urban et al., 2009). The direction of these relationships differed by gender. When they engaged in extracurricular activities, girls who lived in lower-asset neighborhoods exhibited higher levels of PYD and lower levels of depressive symptoms and risk behaviors. At high levels of activity involvement, girls in high-asset neighborhoods exhibited increased levels of risk behaviors, particularly if they lived in neighborhoods with ample physical resources. The opposite relationships were found in boys. Moderate to high levels of involvement in extracurricular activities predicted lower levels of PYD and higher levels of risk behaviors for boys living in lower-asset neighborhoods. For boys living in high-asset neighborhoods, activity involvement was generally beneficial. Increased activity involvement was associated with increased levels of PYD and decreased levels of risk behaviors. The findings from this study pointed

Figure 1 A relational, developmental systems model of the individual ↔ context relations involved in the Lerner and Lerner conception of the PYD developmental process. PYD = positive youth development.

to the need to consider the influence that multiple contextual influences can have on development.

In a follow-up study to work by Theokas and Lerner (2006), analyses by Bowers et al. (2011) assessed the relationships between these ecological assets and trajectories of positive and problematic development. Assets at the family, school, and neighborhood levels differentiated goal-optimization trajectories, while factors at the school level differentiated delinquency trajectories. However, an ecological asset was not found that consistently differentiated both goal-optimization trajectories and delinquency trajectories. The results indicated that collective activity in the family best predicted membership for the five goal-optimization trajectories that were identified, whereas school-based assets (physical resources and accessibility) differentiated the four delinquency trajectories that were identified.

The 4-H Study data have also been used to examine more specifically the ecological assets of parenting and youth programs in relation to the youth intentional self-regulation. For example, using data from Grades 5 to 8 from the 4-H Study, Lewin-Bizan et al. (2010) found a developmental cascade wherein positive parenting (as indexed by warmth and monitoring) was an important contextual asset predicting subsequent intentional self-regulation, and intentional self-regulation predicted subsequent scores for PYD, which, in turn, positively predicted later youth Contribution scores.

As already mentioned, several studies have also used the 4-H Study data set to examine possible interactions between self-regulatory processes and out-of-school-time (OST) activity participation. For example, Urban et al. (2010) found that both the strengths of youth and contextual resources are involved in thriving. Using data collected from youth in Grades 5 to 7, Urban et al. (2010) explored whether youth intentional self-regulation abilities moderated the effect of participation in OST activities on PYD among adolescents living in neighborhoods with relatively low levels of ecological assets. Overall, Urban et al. (2010) found that youth in these settings who had the greatest capacity to self-regulate (i.e., youth with the highest SOC scores) benefitted the most from involvement in OST activities, as demonstrated through their scores on measures of PYD, depressive symptoms, and risk behaviors. These relations were particularly strong for girls.

Mueller et al. (2011) examined whether the relationship between adolescents' SOC abilities and their participation in youth development (YD) programs in Grades 8 and 9 predicted their PYD and Contribution scores in Grade 10. Results indicated that while self-regulation skills alone predicted PYD, self-regulation and YD program participation both predicted Contribution. In addition, Grade 8 YD participation positively predicted Grade 9 SOC, which, in turn, predicted Grade 10 PYD and Contribution.

Conclusions

The results of the 4-H Study of PYD (as well as other research relevant to the PYD model; J. Lerner et al., 2012) provide important insights into what constitutes PYD and which individual strengths and ecological developmental assets help to promote adolescent thriving. We believe that the relational developmental systems approach used across all instances of the PYD model has been useful in understanding, first, the plasticity of human development and, second, the importance of dynamic relations between adolescents and their real-world ecological assets as promoting thriving among youth.

It would be useful if future research exploring the promotion of PYD adopted a common language and system of measurement for individual strengths and ecological assets. In addition, in order to enhance the understanding of ecological assets, the characteristics of contexts other than YD programs merit further study. For instance, more research should investigate the role of families and schools as ecological assets in promoting PYD. Similarly, contexts such as workplaces or faith institutions should be given more attention (Greenberger and Steinberg, 1986; King et al., 2011). Professionals working with families and schools, as well as employers who hire youth, would benefit from being educated about possible applications of how the ecological assets in these settings can enhance PYD among diverse youth.

Childhood: Anthropological Aspects

Thomas S Weisner, University of California Los Angeles, Los Angeles, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Anthropologists believe that the most important influence in human development is the ecological and cultural setting within which a child will grow up. The anthropological study of childhood documents and accounts for the variety of childhoods found around the world, using comparative ethnographic evidence to test hypotheses about human development. It also studies the mechanisms in child, family, and community life for the acquisition, internal transformations, sharing, and intergenerational transmission of culture. Most importantly, it does this with close attention to the everyday contexts and routines of life, experience, meanings, intentions, and beliefs and goals of the communities, parents, families, and children themselves.

Introduction

The anthropological study of childhood documents and accounts for the variety of childhoods found around the world, using comparative ethnographic evidence to test hypotheses about human development. It also includes the study of the mechanisms in child, family, and community life for the acquisition, internal transformations, sharing, and intergenerational transmission of culture. Most importantly, it does this with close attention to the everyday contexts and routines of life, experience, meanings, intentions, and beliefs and goals of the communities, parents, families, and children themselves.

A thought experiment will illustrate the anthropological point of view about childhood. Imagine a newborn, healthy infant. What is the most important thing that you could do to influence the life of that infant? Most respond by mentioning dyadic interaction with the baby: hold and touch the infant a lot; provide good nutrition and health care; provide stimulation to achieve school success; love the baby; give it wealth and social capital; and so forth. Anthropologists believe that the most important influence in human development is the cultural setting within which the infant will grow up. Where on earth is the child growing up – where did the child end up in the 'birth lottery'? It is how, why, and by whom children are held, loved, fed, stimulated, punished, provided resources, and so forth, and how that varies so widely across human communities, that is, the focus of inquiry. Shaping a whole person engaged in family and cultural community life is the purpose of childhood development from an anthropological perspective. Childhood is a cultural project with goals, meanings, constant adaptation, and struggle, and anthropology provides the evidence for the startling and remarkable varieties of childhoods found around the world. Biological, psychological, and cultural anthropologists collaborate in the study of childhood, since biology, mind, and the cultural context are all required to understand childhood (Weisner, 2011).

The study of childhood and the process of children acquiring culture was almost entirely neglected by anthropologists until after 1925 (Whiting, 1968). Although a great deal of progress has been made, anthropology does not yet provide a single unified theory of why and how childhoods vary around the world or of childhood acquisition of culture. Rather the field offers rich, multivariate hypotheses and data on childhood (Super and Harkness, 1997).

The Stages of Childhood

Five stages of human growth and development are common to *Homo sapiens*: infancy, childhood, juvenility, adolescence, and adulthood (Bogin, 1999). Margaret Mead described lap children (infants, aged 0–1), knee children (toddlers, 2–3), yard children (preschool, 4–5), community children (juveniles in middle childhood, 6–12), and adolescence (Schlegel and Barry, 1991). These are maturational periods of development, alongside which cultural groups provide their own varied categories and marked stages of life. A new stage perhaps has emerged for study in the United States and some other Western, developed countries: emerging adulthood, the period from about age 18 to 25 or so, during which marriage may be delayed, education extended, and a search for work and identity continues (Arnett, 2011). Anthropologists analyze the cultural meaning of the very idea of stages, since they are used to account for children's behavior ('he's crying, but it is OK, because he's still a toddler'), as well as to assure and define normal and appropriate development ('she is eight and, so, old enough to start helping run our household'). Human cultures weave wonderful variations, meanings, and stories around panhuman maturational stages of childhood. The Beng of Ivory Coast, for example, believe that young children are still partly in yet another stage, a cultural world called *wrugbe*, where ancestors share life with prebirth children who are ambivalent about leaving that world. This helps explain for Beng why infants cry or are sickly: they want to return to *wrugbe* (Gottlieb, 2004).

Along with these maturational and social stages, evolution has prepared children and their caregivers to seek out information from the environment in all its many forms, cultural and noncultural. There is no question that despite the remarkable variation in parenting and children's learning environments around the world, children and adults alike are

prepared by evolution to be what Melvin Konner (2010) has called 'culture acquisition devices,' or CADs. Thinking of children as uniquely prepared by our evolutionary past to respond to and learn from the environment is a useful way to think about the continual interactions between our genetic inheritance and the importance of the cultural learning environment (CLE). Konner (2010) outlines 20 of these CADs or putative mechanisms that evolved to acquire cultural knowledge. These are divided into four broad categories of these learning mechanisms that are involved in the acquisition of culture: reactive processes in the cultural surround (such as classical conditioning, or social facilitation due to reduced inhibition, or instrumental or intentional conditioning); social learning (such as scaffolding, mimicry, imitation, and direct instruction); emotional/affective learning processes (attachment processes, along with positive or negative identification, or emotional management through rituals and scripts); and symbolic processes (cognitive modeling, schema learning, narrative, and thematic meaning systems).

Conceptions of Childhood in Anthropology

There is a variety of perspectives on childhood in anthropology. In one view, children are socialized into a set of norms and customs that they learn and then perpetuate. In this view, children are small adults in the making, ready receptors of traditions, shaped by parents and community adults to insure continuity in cultural and moral education, provide competence for survival in the ecology of the community, respect for tradition and appropriate behavior, and respect for elders in demeanor and gender roles.

In a second view, children's personalities and minds are understood as reflections of the cultural themes as well as the anxieties children grow up with (such as in the work in Bali of Bateson and Mead, 1942). The focus also is on the semiotics and communication of cultural meanings to children and on how these cultural patterns are absorbed and internalized, which in turn reproduce the meanings as well as neurotic obsessions and conflicts of their parents' cultures.

Third, the psychocultural, or personality integration model (Whiting and Whiting, 1975) begins with the climate, history, and ecology of a community, which shapes child-care practices, which in turn produce psychological effects on children. These contextual influences on children are produced by direct social learning as well as by psychodynamic processes shaping personality and defenses in children. These children become adults who then project into myths, rituals, art, and other forms (including in turn their own practices as parents) of the learned patterns, as well as intrapsychic conflicts produced in childhood and shared by others in their community.

The psychocultural model does not depend on a psychodynamic theory of learning. Children and adults alike have universal needs of the self, including the hunger for recognition, reward, and material and bodily satisfaction, to which communities respond through the cultural careers made available to children in a community. This core, psychocultural motivational force has been described as *affect hunger* by Walter Goldschmidt, who argues that this underlying need drives children to voraciously acquire cultural knowledge and also drives their parents and others to want them to do so (Goldschmidt, 1992). The desire for social recognition and inclusion more generally insures that most individuals link to and engage with society; however, culture channels these desires and, so, inevitably thwarts these needs, leading to intrapsychic and cultural conflicts. Melford Spiro, for example, used both psychodynamic and sociocultural approaches to understand the ideological, political, and ecological reasons for and consequences of the care of children by designated community caretakers, or *metapelets*, in socialist-inspired agricultural collective groups in Israel (Spiro, 1975).

Fourth, anthropologists study the 'developmental niche' of childhood: everyday physical/social settings, cultural customs of care, and the psychology of the caretakers of children. The cultural models of parenthood that are part of the customs and psychology of care direct behavior in their local, everyday settings (which include the goals, meanings, and rationales for parenting and being a child) (Harkness and Super, 1996). Parenting of children also is shaped by the organic hardware given by our common mammalian heritage and by socioeconomic conditions in the community. Children experience culture as it is practiced within their family's daily routine of cultural life. Cultural routines consist of activities children engage in (mealtimes, bedtimes, family visits, chores, going to church, school, play, etc.). Activities are the primary mechanisms bringing culture to and into the mind of the child, since cultural activities are what a child directly experiences day in and day out, repeated thousands of times. Activities consist of goals and values; tasks of an activity; the scripts for how to engage in that activity; the people present and participating in the activity and their relationships with the child and with one another; the motives and feelings and affective and emotional experiences of those involved; and the stability and persistence in the lives of the child and family (Weisner, 1996).

A related concept to the developmental or ecocultural niche is the CLE (Edwards and Bloch, 2010). The CLE consists of a cultural activity in progress, occurring in a social setting in some ecological and historical context, with norms of behavior for that activity and with characteristic people and relationships in the settings. Many features of the CLE have been shown to influence children's social behavior and mind. For example, gender, status in the community, resources, age, family structure (nuclear or extended), formal education, and other features all influence the amounts and ways of expression of children's prosocial behaviors, aggression, nurturance, and other outcomes.

Cultural and ethnic group identification, and the child's and family's own strength of social identity, is an important influence both of a child's own self and, therefore, of the child's and family's connections to the cultural community. Families often are the context in which this sociocultural identity is acquired and experienced due to co-residence, shared surnames and language, and similarity of physical appearance, among other features. The more this social identity is tied to provision of resources and support, and the more salient it is, whether due to external threats or opportunities or a positive sense of a shared heritage, the greater the importance the cultural community has in a child's development.

Finally, some anthropologists view childhood itself as a cultural construction shaped by forces within as well as outside a single cultural community. The very idea of what a child or parent is, in this view, is more the outcome of processes of power in an increasingly global political economy, in which children as well as parents are *constructed* or *positioned* by these agents of power (the state, market economy, political and other elites, and other economic and political forces) (Stephens, 1995). The emphasis of this approach also is on the child as active agent or engaged actor in defining its own socialization. This view counters the idea that socialization and enculturation is done primarily to the child. Culture acquisition also depends on the child's active, often thoughtful participation as well. Children can and do resist what family and society want for them and want of them, and this process of resistance and transformation is an important perspective in anthropology.

Anthropology has contributed to our understanding of formal education through work on classrooms and schools, showing the cultural influences on how teachers teach and manage classroom behavior. Anthropology broadens the study of 'education' to include all forms of social and cultural learning outside of schools, however, and how this much broader world of everyday learning connects with formal classroom learning (Lancy et al., 2010). Anthropological studies also include nonformal and informal education as well as formal schooling, such as out-of-school activities (clubs, music, church groups for children and youth, sports, gaming), various forms of private and commercial schooling (other than formal education), and the intersections between these various settings for learning that are common everywhere.

Some Cultural Influences on Children's Development

Cultural Scale and Complexity

Children in more complex societies (with occupational specialization, an extensive market economy, a nucleated settlement pattern, centralized and hierarchical political and legal system, and a centralized religious priesthood) are more likely to seek help and assistance from others, to try and dominate or control others, and to be more egoistic. Children in less complex societies are more likely to show nurturance toward other children (to offer assistance and respond to their requests), be more responsible, make more responsible suggestions to others, and do more tasks required for family and community survival. Mothers who have heavy subsistence workloads are more likely to expect responsible work from children and use stricter discipline. Children living in extended, joint, or expanded households and family systems are more often involved in directive, aggressive interactions, while children living in smaller nuclear families are more often engaged in sociable and intimate interactions with parents and others. Additionally, fathers in smaller conjugal households and family systems are, on average, more involved with children compared to fathers in joint/extended families.

Of course, children and adults everywhere seek help, show responsibility, or are aggressive and so forth. These patterns only reflect the modal tendencies of communities, not a rigid uniformity within them (Whiting and Edwards, 1988).

Gender Differences

Gender differences in children's development are recognized and shaped by all cultures (Ember, 1981). Of five kinds of interpersonal behavior in children aged from 3 to 11 (nurturance, dependency, prosocial dominance and affiliations, egoistic dominance, and sociability), girls on average were more likely than boys to be nurturing toward others, while boys were more likely to be egoistically dominant and aggressive than girls. Play styles and types of play vary by gender (girls are more likely to do joint work-play and to do so nearer their homes, for instance). Women and girls do most caretaking of children during the juvenile period in most cultures, so girls experience care by their own sex, while boys do not, leading to differences in early gender identification and psychosocial and self-development. Peer groups have a tendency to segregate by gender, and children in middle childhood tend to prefer same-sex children to interact with where there is a choice. Cultures with more mixed-age and mixed-gender groups in settings around children are likely to have less sex-segregated roles for children. Individual differences among boys and girls are usually substantial, even within communities where there are strong overall gender differences in development.

Father roles are recognized in all societies (Shwalb et al., 2013). Fathers seldom are involved in direct care of infants and young children in most societies, but they do have complementary nurturing and affiliative roles. Fathers also are more likely to be involved in economic, protective, and didactic child training. In a study of 80 preindustrial societies, fathers were more often nearer to and involved with young children in monogamous, nuclear family, and non-patrilocal residential situations and in sociocultural circumstances where mothers make relatively large contributions to family subsistence. Father involvement is related to sociocultural evolution: foraging societies report more father participation in childcare, while horticultural, agrarian/peasant, and pastoral subsistence-based societies have tended to have less. There is an upswing in contemporary societies in encouraging paternal care. The cultural beliefs about gender (how women's as well as men's roles are defined by parenting), as well as the ability of fathers to provide consistently for their children, influence father involvements. Poverty and uncertain economic life, or migration and dislocation, can drastically change father as well as mother involvement in patterns of childcare.

The study of gender continues to broaden in scope to include anthropological studies of the trafficking of girls for sexual exploitation – a growing world problem. There is selective abortion practiced around the world, which favors male births over female. Anthropology also is focused on the education of girls and the consequences of that education for a broad range of outcomes. For example, LeVine et al. (2012) ask why there is a correlation between increasing education for girls and women and gradually declining fertility rates and improved health for those women with more formal education and the communities they are in. Although the association has been known for a long time, the mechanisms

were not. Girls' and women's education and literacy provides tools and mechanisms for increased interactions with health and other bureaucracies regarding managing family size, birth control, and family health. These women also are more likely to recognize and practice birth control and wider birth spacing and to socialize their own children using more pedagogical child-rearing practices.

Emotional Development

Emotional development in childhood is influenced by cultural expectations at each developmental stage about the demeanor expected by boys or girls of that stage in particular cultural settings. A child should show that he or she is a certain kind of cultural person with an appropriate self and identity in his/her emotional comportment. Cultural management of emotion relies on what Robert Levy (1973), in his study of Tahitians, called *redundant cultural control*. Tahitians, for example, as well as many other Pacific Island communities, expect children to be calm, gentle, and quiet in demeanor (except for an extended period of adolescence and youth called *taure'are'a* in Tahiti, in which adventures, autonomy, rebellion, and aggressiveness are culturally expected and common). Redundant community management of 'gentleness' includes many beliefs and practices: children are somewhat distanced from their mothers and fathers after infancy and spend much of their time with peers; socialization networks are diffuse, meaning that affect toward others also is diffused; severe anger is strongly discouraged, while mild transient episodes are tolerated; threats are common, while actual aggression toward children is not; accidents are reinterpreted as punishment by spirits for aggression; there can be magical retaliation for serious anger; and, it is generally shameful to show lack of control. A culture complex of many interrelated beliefs and practices of this kind, such as the Tahitian example, including lexical labeling of the expected behavior patters, recognized cultural scripts, and stories adding to its emphasis, all are strong signs that some emotional pattern or competence in children is of adaptive and moral importance to a society.

Ochs and Izquierdo (2009) have tied emotional development to processes of learning responsibility and a sense of obligation and respect. There are clear differences in how communities socialize their children for responsibility and task performance around the world. The US middle class is unusually low in accomplishing such training in responsible tasks for their children compared to many regions of the world.

Basic Trust and Attachment

Another example of cultural variation in development comes from studies of basic trust and attachment. The universal socialization task for cultures regarding attachment concerns the learning of trust, rather than insuring the *secure* attachment (as defined by particular psychological scales) of an individual child to a single caretaker in a dyadic relationship. The question that is important for many if not most parents and communities is not, 'Is (this individual) child securely attached?', but rather, 'How can I insure that my child knows whom to trust and how to show appropriate social connections to others?' 'How can I be sure my child is with others and in situations where he or she will be safe?' Parents are concerned that the child learns culturally appropriate social behaviors that display proper social and emotional comportment and also show trust toward others.

Successful attachment does not depend on only one kind of maternal care in nuclear families, nor a specific kind of infant and toddler behavioral style. Anthropological studies show that a wide range of family and parenting practices found around the world can produce close affiliation and trusting attachments in children (Otto and Keller, 2013; Quinn and Mageo, 2013). Although the individual child is named and recognized everywhere (this is the basic process of individuation), individualism and egoistic autonomy as goals clearly are not universal. Sociocentric and interdependent self-development is more common ideals in much of the world compared to autonomous and independent development (Shweder and Bourne, 1991).

Chisholm (1999) proposes an evolutionary developmental hypothesis regarding trust and attachment. Considering the long course of evolution, children and families faced highly changing kinds of environments. These environments varied in how risky, uncertain, and variable they were. Less threatening, more favorable material and social conditions led to greater investment in fewer children and, so, encouraged closer attachments to one or a few caregivers. Unfavorable conditions encouraged what are labeled (inappropriately so from an anthropological perspective) *insecure* or avoidant/ambivalent infant and child behaviors observed during standardized assessments or rated through interviews or questionnaires. In threatening, insecure conditions, those often were the more adaptive, successful parental and child responses that were likely to increase the chances of children reaching reproductive age.

Multiple caretaking is found widely across communities around the world (Weisner and Gallimore, 1977). Most cultures provide multiple caretakers to children, rather than a single person. Care is socially distributed across many in the family and community in most children's lives, not dependent on a single person. Indeed, a child living an entire childhood exclusively in his or her natal home may well be the exception around the world. Older siblings and cousins are widely used as caretakers as well as other kin, hired care, and group care. Extended families in village and agrarian-based societies have high levels of multiple care of children. In India and elsewhere in Southeast Asia, for instance, there is an intense childhood experience with several maternal figures (Seymour, 1999). This means that a focus on a single dyadic connection as the key indicator of 'secure' emotional attachment does not fit the experience of most children and caregivers, nor evolutionary evidence (Hrdy, 2009).

Many communities (particularly more hierarchical, agrarian/horticultural, and respect-oriented) want infants and children to exhibit calm, respectful, quiet demeanor in the presence of strangers and community members generally, and there is evidence from the Nso of Cameroon, Gusii of Kenya, and many other societies that even very young children learn

and display this relationship style. This is not a sign of insecure attachment (Keller, 2012; LeVine and Norman, 2001). Learning about trust and security in many communities includes socialization for respecting hierarchy, showing deference, and training children to not expect parental responsiveness and warmth, as Jeannette Mageo has shown for Samoan family life (Mageo, 1998). Mageo suggests that achievement of group trust and attachment is not based only on a positive feeling of security. Trust and relational security may well include experiences of ambivalence and even avoidance of some family and kin, as well as acceptance within the group, including kin and community support. Similarly, managing anger and expecting and accepting only intermittent maternal attention are believed to be the appropriate training for learning how to anticipate and deal with security and separation among the Murik of Papua New Guinea (Barlow, 2004). The Murik do provide early mother-specific attachment socialization, which is closely tied to nursing and the provision of food. They also emphasize the diffusion of emotional relations outward to other caretakers (siblings and kin), who generally are harsher and who discipline the young child most often (rather than the mother). The Murik cultural intention is to complement the one with the other kind of care. The cultural message is that both of these kinds of caretaking experiences are needed for true, realistic emotional security in the Murik world. Both patterns certainly are what Murik will face in life. Hence, both patterns are emphasized and defined as good mothering and secure attachment. To be pluralistic and situation-centered, not only person-centered or dyadic relationship-centered, is an important component of the socialization for trust and a sense of security in most communities.

Developmental Goals

Anthropology does not assume that competencies valued in Western communities (verbal skills, cognitive abilities, or signs of egocentric autonomy of the self, for instance) are necessarily desired or even meaningful child developmental outcomes elsewhere (LeVine, 1988). However, nearly all cultures are concerned over some version of good communication, mental ability, self-construal, and personhood. LeVine et al. (1994) contrast *pedagogical* goals (cognitive and social stimulation to prepare children for literacy and schools, as well as for an individualistic and autonomous self-construal) and *pediatric* goals (concern for survival, health, and physical growth of infants, and subsequent responsible engagement in family subsistence and family continuity). Of course, in the contemporary world, many parents and communities want a hybrid combination of these goals for their children (Edwards and Whiting, 2004).

Anthropology has a unique point of view regarding the goals for a good childhood: the production of cultural well-being in children. Well-being is more than physical health, the attainment of skills and competence, the absence of illness or misfortune, or of successful subsequent reproduction, important as these are. Well-being is the ability of a child to engage and participate in the activities deemed desirable by a cultural community and the psychological experiences that go along with that participation.

The Acquisition of Culture

The roles and settings in which children learn of course influence when and how children will acquire cultural knowledge. Children are apprentices to more experienced community members in doing important tasks, and this apprenticeship situation is a powerful learning experience for children. Play and work blend in childhood learning. Imaginative, fantasy, toy, physical, and motoric kinds of play (including organized sports with rules) vary according to whether adults encourage it or whether it is considered beneficial for children by adults because they believe that it enhances desired competencies or furthers their societies' developmental goals (such as cognitive and school-like activities in many contemporary cultures). Of course, play is universal among children, as soon as their sheer inventiveness, creativity, and exuberance take over.

Adults are rarely involved in play with children in most societies around the world, in contrast to the emphasis on adult-child play from early childhood on in the United States and other Western, developed countries (Lancy, 2007). For example, the Kpelle of Liberia in the 1970s had children playing on 'the mother-ground,' or open public spaces where children can observe, lurk nearby, and imitate adults going about their activities in their agrarian village community. Formal schooling contrasts sharply with this mother-ground of childhood and everyday learning in context. Anthropological studies of schooling find striking differences in the culture of classrooms around the world, including different teaching practices and student expectations. A moral and cultural curriculum accompanies the formal literacy, numeracy, and sciences training in classrooms. Preschool classrooms around the world reflect implicit cultural models regarding the importance of collective, group activities (in contrast to more individually chosen activities preferred in many US preschools). For example, US teachers intervene and use words to negotiate disputes, while Chinese and Japanese classrooms monitor and encourage children to settle their own disputes. There are many other such national/cultural differences (Tobin et al., 2009). Participation in ceremonies and rituals at times of baptism, birthdays, naming ceremonies, puberty, and marriage also has powerful influence on children's acquisition of cultural knowledge. Such ceremonies crystallize cultural beliefs and practices. They intensify emotionally, politically, and socially salient key concerns that parents and communities have about childhood and elevate the goals the community shares for children and parents (Turner, 1967).

Multiple cultural and mental processes are involved in culture acquisition; however, the relative importance of different mental and cultural mechanisms for emotional, social, or cognitive learning are currently not well understood in anthropology. Evolved tendencies of the mind prepare children to understand the world in certain ways. For example, children in widely disparate cultural communities seem to share understandings about what living things are like and how they behave and think (Hirschfeld and Gelman, 1994). Psychodynamic processes transform emotionally salient cultural information. Stories and narratives embed cultural knowledge, shape recall, and organize cultural knowledge into scripts with shared local meaning. Sociolinguistic studies

of child language acquisition show wide variations in how and when parents talk to their children. Language learning is embedded in interactional routines shaped by cultural practices, with children as active learners (Schieffelin and Ochs, 1986). Children's play, games, and language use show strong evidence of class and race/ethnic influences as well as cultural knowledge. Children display remarkable creativity and agency and use the richness of language in shaping social relationships, beliefs, and practices (Goodwin, 1990). Neither children nor parents generally have explicit, conscious awareness of all the complex cultural knowledge that they know. Most cultural scripts are seldom in conscious awareness, even as they drive actions in accord with their community's beliefs. Cultural beliefs and practices have powerful *directive force* in guiding child behavior and child socialization in part because of this shared, implicit, everyday understanding put into action (D'Andrade, 1995; Lancy et al., 2010).

Anthropological Methods and the Study of Children

Anthropological methods for the study of children include qualitative interviews and conversations, ethnography, and participant observation (Weisner, 1996). These methods are important for operationalizing the anthropological concept of childhoods lived in cultural pathways in naturalistic settings. Systematic observational procedures, field guides for comparative studies, and special procedures for sampling children's activities and time use enhance ethnography (Bernard, 1995; Munroe and Munroe, 1994). Anthropologists also use assessments standard in child development for comparing physical growth and the cognitive and socioemotional life of children, often revising these standardized measures to insure that culturally appropriate procedures and meaningful outcomes are being measured. The processes of language-mediated culture acquisition, using sociolinguistic methods, are essential to understand the process of 'becoming a speaker of culture' (Ochs, 2002) and are central in anthropology. Film and video records of childhood are invaluable for comparative studies of cultural activities, emotional expression, daily routines and activities, the physical environment of the home, and patterns of gaze and attention, for example (Ochs and Kremer-Sadlik, 2013).

The cumulative cross-cultural ethnographic record of the lives of children and parents around the world is a unique, invaluable, and remarkable contribution to the scientific study of childhood and human development (Lancy, 2008; LeVine, 2007). The use of ethnographic and qualitative evidence in the contemporary study of children's lives is also increasing throughout the social sciences (Yoshikawa et al., 2008; Weisner, 2011). Using these methods for studying children's lives insures that the social, cultural, and ecological context of children's lives is fully included in the study of child development, and that the experiences, meaning systems, and intentions, goals, and values that influence the developmental pathways available to children are never excluded from study. For analytic reasons, it is, of course, important to bracket context out, and use a wide range of methods for study, but anthropologists do not forget that the world is not linear, additive, and decontextualized. Anthropological methods therefore will always be essential (Weisner and Duncan, 2013).

Anthropology and the Study of Childhood in the Twenty-First Century

Anthropology has always been concerned with the experiences and the cultural worlds of minorities, of the poor and nonliterate, and of those, including children, who are so often unable to give voice to and represent their own world. Life histories and autobiographical accounts of childhood have provided rich data, as in the classic *Nisa: The Life and Words of a !Kung Woman* (Shostak, 1981). Scheper-Hughes (1992) describes infants and young children in deeply impoverished political and economic circumstances in northeastern Brazil, circumstances leading to high infant and child mortality, and anger and despair among parents (and anthropologists). Anthropological studies of African-American families and economically downwardly mobile families in the United States demonstrate how some (but not all) can rely on extended kin in their struggles with poverty. Anthropological studies of childhood disability and deviance find greater acceptance and social integration of children with physical and cognitive disabilities in many communities than in the United States and other Western societies, as long as children are able to live as sufficiently cultural persons in their communities and are not violent or dangerous to others (Ingstad and Whyte, 1995). Disability and mental health usually are considered by anthropology in the context of other sources of poverty and social exclusion along with the disability or mental illness itself.

Anthropologists are concerned with children at risk around the globe, including children under stress from academic examinations in Japan and Korea, immigrant children in Europe and elsewhere, including street children, or children facing war, forced migration, and economic exploitation due to globalization and other change in Africa and elsewhere. Child sexual and physical abuse around the world is now a recognized concern for anthropologists. Cultural beliefs and practices regarding appropriate discipline and treatment of children clearly do vary widely, and Western notions of abuse are not universal; however, repeated and unchecked physical aggression or intrafamilial sexual relations between close kin and children are nowhere defined as normative and acceptable (Korbin, 1981). Anthropologists are concerned with children's rights, recognizing their vulnerable status and the lack of provision of basic protections for children (*Cultural Survival Quarterly*). World youth cultures are growing in importance due to the influence of the Internet and mass communications around the world. The recognition of and attention to children who are deprived, vulnerable, and excluded for a wide variety of reasons continues to be a central concern for anthropology. These are all topics for the anthropology of childhood in the twenty-first century (Weisner and Lowe, 2005).

Globalization is an important force in the world today. Nonetheless, regional, cultural, and family system differences remain very powerful. Rogoff (2011) illustrates this remarkable

blending of tradition and change in a Mayan village in Guatemala across four generations, as does Greenfield's multigenerational study of weaving, child development, and economic change in Southern Mexico (2004). Ngecha, a Kikuyu community in periurban Nairobi, Kenya, shows three generations of continuity as well as dramatic changes in education, work, and state-level change. The roles of women in this community are a key to understanding these changes and their consequences for children and family life (Edwards and Whiting, 2004).

More generally, Therborn (2009) characterizes seven broad cross-cultural family patterns that clearly persist and influence anthropological studies of children and families today and will continue to do so for the foreseeable future: Christian European; Islamic West Asian/North African; South Asian Hindu; Confucian East Asian; sub-Saharan African; Southeast Asian; and Creole (U.S. South, Caribbean, Brazil, parts of South America). Each of these seven broad family patterns differs in social dimensions that have profound influences on the pathways of social development for children growing up within those family systems. These highly culturally variable dimensions of family systems include norms concerning inheritance (e.g., whether all children inherit equally, or only males, or only firstborn males) or descent rules (e.g., bilateral as in the United States or patrilineal) and marriage customs that are preferred or permitted in different communities (e.g., whether there is an ideal norm of lifetime monogamy; whether divorce and serial monogamy are allowed or plural marriage is permitted). Beliefs about sexuality and gender and patterns of household formation also vary systematically across these family regions (i.e., whether couples form independent households, live with parents, or form joint or extended households; whether children typically remain in one household or move between multiple households during childhood). Influences of religious practices on families and many other norms, laws, and customs that shape family life show similar patterned variation, and so they deeply affect the developmental pathways of children and youths. As Therborn (2009) comments about the widely varying families around the world, and the lives of children in them, "The boys and girls of the world enter many different childhoods and depart them through many different doors" (p. 338). Along with globalization, the anthropological comparative study of powerful local and regional cultural differences in parenting, childhood, and family life across populations around the world will continue to not only be important, but also to provide enduring scientific questions.

Childhood Cancer: Psychosocial Aspects

Abstract

Medical progress has been able to make many childhood cancers nonfatal. Therapies are now available that turn cancer into a chronic condition or even cure it completely, even if lasting impairments may remain. In Europe and North America, about 80% of all patients with cancer in childhood and adolescence survive their leukemia, lymphomas. or tumors. The improved treatment options and changed ethical approaches have led to a consensus that the child should be told the life-threatening nature of the disease in an honest and age-appropriate way. Psychological research does not focus on suspected psychosomatic causes of childhood cancer manifestation but on the stress impact imposed by disease and treatment and the transactional coping and adaptation process in the child and family. The patient's and the family's adaptation to the challenges imposed by disease and treatment depends on the balance of stress impact, on the one side, and available coping competencies and resources, on the other side. A psychological intervention program is introduced that focuses on counseling and supporting the family across different treatment phases (initial phase of diagnosis; intensive oncological treatment; long-term remission of the disease and reintegration of the child versus, in case of a negative disease course, recurrent relapses, and final death). Key interventions refer to the enhancement of open and clear family communication including mutual exchange of personal needs and concerns and the practical organization of day-to-day routines as well as an effective communication with the healthcare team or with the social network. During the last decade, psychological research has shifted toward the long-term psychological outcome in survivors of pediatric cancer patients. The risk of neuropsychological impairments, psychopathological comorbidity, and potential impairments of health-related quality of life have become complementary parameters for conceptualization and evaluation of modern oncological treatment protocols. A conceptual framework is introduced that delineates mediators of adaptation process and adjustment outcome covering a continuum of emergence of psychopathology (e.g., posttraumatic stress disorder (PTSD)), on the one side versus occurrence of developmental benefit and resilience, on the other side.

Substantial progress in cancer treatment (chemotherapy, radiotherapy, surgery, bone-marrow transplantation) has dramatically improved the long-term survival rates of children and adolescents with the diagnosis of cancer (malignant tumors, lymphoma, and leukemia). Some decades ago, the only probable outcome without any alternative for the family was to face the death and loss of their child. As nowadays more than two-thirds of the young patients survive, cancer in children and adolescents no longer is regarded as fatal but as a chronic disease, which can result in complete cure, death, or survival with potential physical, neurological, neuropsychological, psychosocial, and psychopathological impairments.

To date, a broad consensus is established on telling the child honestly the life-threatening nature of the disease. The statistical survival rates, however, do not determine the particular prognosis in the individual child, turning the former threat of certainty of death into the threat of uncertainty of the very personal fate. The term 'Damocles syndrome' characterizes the psychological situation of the family that has completed oncological therapy but cannot be sure to have definitely defeated the disease.

Psychological Adaptation to Childhood Cancer as a Balance of Stress and Resources

The manifestation of childhood cancer is not associated with any known predisposing social or psychological feature in the child or in the family. Its presence can be regarded a randomly occurring highly stressful life event for 'normal' families. As a consequence, psychological research and intervention in pediatric oncology is not concerned with the detection of suspected 'psychosomatic' causes of cancer but with an understanding of the 'biopsychological' stress impact imposed by cancer diagnosis on the child's and family's psychological functioning and well-being.

The risk for the child or the family to master or to fail in the turmoil of the cancer experience may be compared to a balance with one scale pan containing all the stressors resulting from the disease and the other scale pan containing all the resources, competencies, and sources of social support to handle the stress. In some vulnerable families, strong stressors and demands clearly outweigh only weak resources, thus increasing the probability of emotional suffering and behavioral disturbance in the child as well as the risk of marital discord or parental depression. Other families are characterized by resilience, i.e., the available resources are strong enough to outweigh the threatening disease impact, thus giving rise to good adjustment and a personal sense of mastery. The large majority of patients succeed in mastering the plethora of disease- and treatment-related stressors and challenges (Long and Marsland, 2011).

Enhancement of Effective Coping with Childhood Cancer by Family Counseling

Understanding adaptation to childhood cancer as a psychological balance between burden and resources can serve as a basis for effective psychological counseling strategies. Therapeutic enhancement of adaptation includes two major approaches: decrease stress impact and increase coping

competencies and resource availability. In order to administer individually tailored counseling strategies, a broad knowledge is required on the most common and threatening source of stress, on the one hand, and of the most powerful resource that can be mobilized, on the other hand. Typical stressors imposed on the family and child are presented in Table 1 covering practical, emotional, social, and existential domains. As a counterpart, Table 2 shows resources that can buffer and diminish cancer stress impact, improve adaptation, stabilize quality of life, and protect from mental health disturbances for both individual family members and the entire family system. Research has highlighted the key role of family communication behavior for adjustment outcome at the individual and system level. Intensity and quality of communication between the parents about disease issues is closely correlated with an improved parent–child contact as well as with a high disease-related information level in the child and the siblings. A fair and respectful sharing of the cancer-related burden and tasks is correlated with a high family coherence and stability suggesting mutual pathways (Noeker et al., 1990).

Table 1 Typical stressors, demands, and challenges frequently occurring during the course of childhood cancer

Organization of treatment (meetings with physicians, insurances, etc.)
Financial expenditures
Gathering information on cancer and its treatment
Repeated hospitalizations including the alternative to stay at home with the siblings or be in the hospital with the ill child
Treatment-related distress according to painful and frightening medical procedures (e.g., bone marrow aspirations) and treatment side-effects (e.g., nausea and vomiting due to chemotherapy)
Reduced time for recreation and holiday
Role conflict (e.g., father between ongoing job demands and family need for support)
Reexamination of future perspectives (job perspectives of the mother; schooling of the child)
Sharing responsibility for treatment decisions (e.g., amputation in the case of bone sarcoma)
Subconscious violation, disappointment, frustration of the hope for a normal and healthy child
Religious doubts
Uncertainty of final outcome; fear of relapse, fear of loosing the child

Psychological Counseling Strategies and Interventions across Different Phases of Childhood Cancer Treatment

Psychological counseling programs have been developed based on the knowledge of typical stress and resource factors in families with childhood cancer (Kazak et al., 2007, 2012; Noeker et al., 1990). The particular counseling interventions applied are specifically tailored taking into account the specific stressors that characterize certain phases of the treatment course. Counseling sessions may take place at the clinic or at home. While all family members should join them, there may also be an indication for sessions with family subsystems, e.g., when mother and father want to find out an agreement on consistent parenting behavior. In the following, selected topics and strategies of a psychological counseling program are delineated following the major treatment phases.

Supporting the Initial Coping with Cancer Diagnosis

After being told the diagnosis of childhood cancer, most parents show strong affective reactions like shock, sadness, anger, and despair. The primary task of the counselor here is to support awareness and acceptance of these emotional reactions via verbalization and clarification. Idiosyncratic and biased lay theories of the parents on the reasons why exactly one's own child has cancer have to be resolved as they may interfere with the medical treatment plan in the long run. While exploring subjective disease and treatment concepts, special attention has to be paid to frequent parental beliefs of being personally responsible for and feelings of guilt about their child's cancer (e.g., via genetics, bad food, psychological stress). Cognitive-emotional restructuring of inappropriate disease concepts enhances the parents' cognitive capacity for understanding and accepting the oncological treatment concept.

The next major counseling task is to initiate an active, mutually respectful, and supportive coping attitude and behavior within the family system including:

1. clarifying the kind of support every person in the family needs most from other family members for stabilizing outer and inner equilibrium;
2. encouraging open communication and frank expression of personal feelings, concerns, sorrows, and anxieties among the family members; and
3. promoting an attitude and commitment to approach the new burden and tasks as a shared challenge for the entire family.

From a 'Protective' to an Open Approach

Some decades ago, a so-called 'protective' approach was preferred based on the notion not to disclose the life-threatening nature of the disease to the child. In the meantime, not only ethical considerations but also progress in oncological treatment strategies has led to a broad consensus that there is no responsible alternative to telling the truth even to preschool children. Today, medical progress makes it possible to counterbalance the bad news of cancer diagnosis with the good news of profound hope for cure. Therefore, telling children the truth includes two realistic key messages: first, that death has to be expected if no treatment is performed, and second, that even the treatment does not necessarily guarantee survival. Information given to the child should be appropriate to their cognitive and emotional age and maturity. In small children, showing concrete treatment procedures and instruments and offering plausible explanations for sensory experiences like vomiting during chemotherapy is more effective than abstract explanations about malignant cells. An approach that avoids telling the truth implies serious medical and psychological 'side-effects' to be considered:

1. A child will not accept the enormously distressing treatment procedures without the awareness of the serious consequences in case of treatment refusal. Thus, true information is necessary for compliance with treatment, and compliance with treatment is necessary for medical treatment success.
2. Children who lack plausible information on their condition tend to develop other explanations for the occurrence of their disease (Eiser, 1993). Such a frequently reported belief is that the illness represents a punishment for one's own misbehavior.
3. Trust in the parents is one of the most important psychological resources for the child to protect from feelings of loneliness, separation, and depression. A child uncovering the parents' well-meant lies will not only have to struggle with the adversities of disease and treatment but, in addition, with parental alienation.

Phase of Intensive Oncological Treatment

After the family has overcome the initial shock of cancer diagnosis, psychological counseling should assess vulnerability and resource factors in the child and in the family. Premorbid factors of vulnerability that were already operating during the time before the diagnosis (e.g., behavioral or developmental disorders in the child, intense sibling rivalry, marital discord, inconsistent parenting styles, socioeconomic disadvantages) may interfere with a competent adaptation to demands of disease and treatment. Assessment of premorbid risk factors, therefore, improves the chances for early, preventive and individualized intervention. At least as important as the assessment of risks and deficits, however, is the exploration of strengths, skills, competencies, and resources. If a counselor turns the family's attention to positive experiences of crises that were resolved successfully during the past, problem-solving strategies may be reactivated that have proven specific adaptability in this particular family. Past experience of successful mastery strengthens self-efficacy also toward cancer challenges. Psychological counseling during intensive oncological treatment includes:

1. encouraging active participation in the management of the illness;
2. defining clear and practical responsibilities for the day-to-day management of additional chores and tasks; making sure that agreements are perceived as a fair sharing of the burden by every family member;
3. parenting issues (e.g., ways to show affection without spoiling and pity);
4. mobilization and acceptance of concrete social support from neighborhood or classmates; and
5. facilitating honest communication between family and healthcare team.

Negative Disease Course: Recurrent Relapses, End-Stage of Disease, Death, and Dying

A new diagnosis of recurrent cancer after a time of suspected remission requires similar accepting and verbalizing counseling strategies concerning the intense emotional reactions that have been experienced during the encounter of being informed of the diagnosis. Now the focus of counseling may shift toward the ambivalent tendencies toward continuation versus discontinuation of oncological treatment as the parents may wish to maintain any chance for cure, on the one hand, and may not want to see the child suffer from a stressful but potentially futile treatment, on the other. With the worsening of the child's condition, the threat of loss of the child is gradually intensified leading to the following counseling topics:

1. Preparing parents for communication with the child on death and dying. Finding individually appropriate images integrating truth and hope.
2. Searching for phantasies on a good way to spend the remaining time together; development of other important goals in addition to survival like freedom from pain.
3. Enhancing imagery on a suitable way of parting in dignity.

If the child actually dies, it is important to say that the treatment failed and not the child or the family. The family's engagement shown for the child should be acknowledged. Individually suitable mourning rituals may be conceived that combine keeping related to the deceased child and, at the same time, letting them go. Family members may be encouraged to take their time for mourning and grief according to their very personal needs not according to expectations of their social network (*see* Bereavement).

In summary, many counseling interventions focus on the enhancement of open and clear family communication. The mobilization of this key resource for effective coping with the burden of childhood cancer may refer to the mutual exchange of personal needs and concerns, the practical organization of day-to-day routines, or the subtle communication between parents and child about their chances of survival. Effective extrafamilial communication may refer to establishing cooperation and agreements with

the staff or to mobilizing and accepting support from the extended social network.

Positive Course: Long-Term Survival and Reintegration

After termination of intensive oncological therapy, anxieties remain in patients and their families concerning a return of the disease, which would require a completely new course of therapy with, however, decreased chances for cure. Families suffer from intrusive thoughts and chronic sorrow about potential cancer relapse comparable to symptoms in Generalized Anxiety Disorder. Intervention strategies based on Cognitive-behavioral Therapy (CBT) and on Acceptance- and Commitment-based Therapy (ACT) can support the patient and family members to observe these recurrent thoughts consciously, to accept them as a natural reaction to an abnormal situation, and at the same time, not to get too much involved every time anxious cognitions emerge. Counselor and family may cautiously anticipate and go through possible responses and options for the case of an actually occurring relapse.

Termination of therapy also requires encouragement of the child to give up their sick role and corresponding privileges and to promote social reintegration in previous roles, groups, and obligations.

Long-Term Adjustment Outcome in Childhood Cancer Survivors

During the last decade, a number of patient registries, multicenter studies and *metaanalyses* have investigated the interaction of disease- and treatment-associated risk factors with sociodemographic and psychosocial vulnerability factors in long term survivors of childhood cancer. The Childhood Cancer Survivor Study (CCSS) funded by the National Cancer Institute represents the largest and most comprehensively characterized group of childhood cancer survivors in North America (Leisenring et al., 2009; Zeltzer et al., 2009). The sample includes 7147 (77%) survivors and 388 (78%) siblings. Whereas adult survivors of childhood cancer from the CCSS report more symptoms of psychological distress compared with siblings, both groups report better psychological adjustment than that found in population norms. Survivors report poorer health-related quality of life (HRQOL) in physical and social but not in mental health domains compared with siblings. Compared with U.S. population norms, survivors have increased risk of poor HRQOL in physical and social domains, with the largest effect size in vitality. Previous treatment with cranial radiation and surgery are associated with poor HRQOL, particularly in physical domains. Participants diagnosed <10 years of age or treated in the past 25 years report better HRQOL than those diagnosed >10 years of age or treated >30 years ago. Several studies have indicated that brain tumors and treatment strategies including central nervous system (CNS) surgery, cranial radiotherapy, and intrathecal chemotherapy carry an increased risk for neurological and neuropsychological long-term outcomes, which in turn also threaten the patients' psychosocial and vocational participation.

Developmental Benefit

Threatening and distressing experiences such as the life-threatening condition of cancer do not inevitably exert a detrimental impact on psychological functioning on the contrary, may also enhance personal mental growth and development gains, which predispose to an increased resilience to future crises and challenges. Currier et al. (2009) have developed a questionnaire that reflects both the stressful and beneficial side of pediatric cancer (Revised Benefit/Burden Scale for Children, BBSC). The instrument separates psychometrically two very distinct factors, the perceived stress versus the perceived benefits. Both 10-item scales show excellent internal consistency. In some patients, both scales are highly increased indicating that the very dramatic, vital experience is not simply processed as only positive or negative. Rather, the impressive challenges of disease and treatment include both an intense stress impact and perception of a meaningful life experience. Maybe in some patients the very existential confrontation with the risk of death and dying acts as a precursor for a final strengthening of basic assumptions concerning ultimate personal safety, protection, self-efficacy, and confidence. Studies highlighting positive long-term outcome, however, have been questioned as survivors of cancers may be biased reporters and tend to deny difficulties and overestimate their positive health and satisfaction.

Adjustment between Dysfunction and Resilience

Despite the methodological progress achieved by large multicenter trials and *metaanalysis*, psychological research continues to face the task to disentangle the mediators and moderators that explain the enormous interindividual variation in psychological outcome in childhood cancer survivors, even in the case of high similarity in oncological conditions. **Figure 1** provides a heuristic developmental model that depicts factors resulting in a spectrum of unfavorable versus favorable developmental pathways and adjustment outcomes. As the most unfavorable outcome mental disorders may emerge, often in the form of PTSD, as well as depression or anxiety disorders. The next outcome category refers to patients with physical, cognitive, emotional, functional, or social impairments concerning HRQL, but who do not fulfill the criteria for any specific mental disorder. The next category refers to the large group of patients that do not show differences in psychological outcome measures compared to healthy controls. At the most favorable end of the spectrum, there is the subgroup of patients that show developmental benefits and increased resilience.

As illustrated in **Figure 1** the adjustment outcome in the individual case depends on the interaction of disease- and treatment-related factors, on the one hand, and psychological factors of premorbid vulnerability and patterns of the transactional process of coping with disease- and treatment-related stressors, on the other hand. The individual pattern of premorbid cognitive-emotional schemata and behavioral skills predisposes to a higher or lower coping capacity and,

Figure 1 Differential developmental paths and outcomes in survivors of childhood cancer.

finally, coping success. Cognitive appraisals and coping behavior may be altered by neuropsychological impairments acquired by brain tumor or CNS surgery, radiation, or chemotherapy.

A key assumption underlying this model is that of a continuity or even enhancement of premorbid adjustment levels by the impact of living with the cancer experience. Patients with a high level of premorbid resources and coping skills are likely to take a developmental path toward uncompromised mental health or even developmental gain. Patients with a premorbid vulnerability, however, carry an increased risk of coping failure and negative (traumatic, depressive, anxious) reappraisals and conclusions drawn from the cancer experience. Negative inferences promote dysfunctional belief systems increasing the risk of adjustment failure and final psychopathology.

Childhood Memories

Abstract

During infancy and early childhood, what we encode and remember is stored, retained, and retrieved, largely without the benefit of language, but during the rest of our lives, our memories are established, maintained, and expressed using our extensive language networks. In this article, we will introduce a few experimental procedures that can be used to study the transition between nonverbal and verbal memory processing during early childhood and discuss the long-term fate of early childhood memories.

Humans are the only animals who, over the course of their lifetime, make the transition from encoding their memories in a nonverbal format to a format that is primarily based on language. During infancy and early childhood, what we encode and remember is stored, retained, and retrieved, largely without the benefit of language, but during the rest of our lives, our memories are established, maintained, and expressed using our extensive language networks. What happens during this important transition from one representational format to the other? Are we eventually able to translate some of our early preverbal memories into words as we acquire our native language? And, if we can, under what conditions might this translation occur?

Historically, research on memory development has typically been conducted in two distinct ways – researchers who study infants and young children have relied exclusively on nonverbal learning and memory techniques, while researchers who study older children, adolescents, and adults have relied primarily on verbal procedures instead. The goal of this article is to explore the transition between nonverbal and verbal memory processing during early childhood. Our specific aims are twofold. First, we will compare children's nonverbal and verbal memories of the same event. Second, we will review what we know about the fate of memories that were originally encoded largely without language.

Nonverbal Memory Procedures

Given human infants' preverbal nature, the study of memory processing by them has relied exclusively on nonverbal procedures. In the past, researchers have used the visual paired-comparison (VPC) paradigm (e.g., Fagan, 1974; Fantz, 1964; Rose, 1981), operant conditioning techniques (e.g., Hartshorn and Rovee-Collier, 1997; Hartshorn et al., 1998; Rovee-Collier et al., 1980), and imitation tasks (e.g., Barr et al., 1996; Bauer and Shore, 1987; Meltzoff, 1985) to study memory development beginning from birth to the age of 3 (and sometimes even older). In these tasks, nonverbal instructions are built into the procedure such that participants know what to do in the absence of verbal instructions, and participants can 'show' rather than 'tell' us what they remember. The results obtained using these three nonverbal tasks are highly consistent. Across all three, retention increases as a function of age, the range of effective retrieval cues increases as a function of age, and memories that appear to be forgotten can be reactivated and expressed given the appropriate retrieval cues (for a review, see Hayne, 2004).

Verbal Memory Procedures

As children begin to acquire language, researchers typically employ verbal memory procedures similar to those used with older children and adults. In these studies, children are asked to 'tell' rather than to 'show' what they remember. Katherine Nelson was one of the first researchers to ask children about familiar, past experiences (for a review, see Nelson, 2006). Since her pioneering studies, verbal interview procedures have been used extensively with preschool-aged children who have been asked to recall both repeated (e.g., Fivush, 1984; Hudson and Nelson, 1986) and unique events (e.g., Farrant and Reese, 2000; Fivush et al., 1984, 1987; Gross and Hayne, 1998). Collectively, these studies have shown that children begin to talk about the past beginning at about 18–24 months of age, the length and organization of their past-event narratives increase as a function of age, and, as with measures of nonverbal memory, the duration of retention increases as a function of age (for a review, see Nelson and Fivush, 2004).

Despite the wealth of knowledge that we have accumulated about nonverbal and verbal memory development during infancy and early childhood, what we lack is a clear understanding of whether memory processes change when children make the transition from one encoding format to another and, if change does occur, what the nature of that change might be. To address this issue, researchers have recently developed a number of 'blended' memory techniques that incorporate both verbal and nonverbal tests. In this article, we will review some of the studies that have used these blended memory procedures and present findings that provide key insights about the continuities and discontinuities in memory development during the transition from infancy to childhood.

Blended Memory Procedures

Hide-and-Seek Task

The hide-and-seek task was originally developed by DeLoache and Brown (1979) as a measure of nonverbal memory in very

young children. At the time the task was developed, work by Rovee-Collier and her colleagues had already shown that infants as young as 3 months of age exhibited retention after delays as long as several days when tested using the mobile-conjugate reinforcement paradigm (e.g., Rovee-Collier et al., 1980, 1981). Ironically perhaps, comparable evidence for long-term memory of toddlers and young children was extremely limited (e.g., Daehler et al., 1976; Horn and Myers, 1978). Importantly, the hide-and-seek task provided some of the first evidence for memory over periods longer than just a few seconds in very young children.

In the basic hide-and-seek task, children are told that a stuffed toy (e.g., Big Bird) is going to hide, and they are encouraged to remember where it is hidden so that they can find the toy later. The child then watches the experimenter hide the toy in a specific location in their house (e.g., under the bed). After a delay of approximately 5 min, during which the child and the experimenter engage in another activity, the child is then asked to retrieve the hidden toy. Using this procedure, DeLoache and her colleagues found that children as young as 18 months of age have robust memories for the location of hidden objects (DeLoache and Brown, 1979, 1983, 1984; DeLoache et al., 1985).

Although the original hide-and-seek task was used as a purely nonverbal measure of young children's memory, more recently, we have extended the task to include both nonverbal and verbal measures. In addition, with the aim of using the hide-and-seek task as a measure of children's episodic memory, we modified the task such that it would allow us to test children's recall of the three W's of episodic memory (Tulving, 2002): the what, when, and where of the hiding event. In our modified version of the hide-and-seek task, the experimenter first familiarizes the child with seven stuffed toys (Donald Duck, Ronald McDonald, Mickey Mouse, Eeyore, Bert, Bob the Builder, and The Count). The child then chooses three toys and accompanies the experimenter to hide each of the three toys in a specific location in separate rooms around his or her house. When entering each room, the experimenter asks the child to name the room and to watch carefully as she hides the toy. Once all three toys are hidden, the child and the experimenter return to the living room and read two books during a 5-min delay to prevent children from rehearsing the hiding locations. Immediately following the delay interval, the verbal recall test is administered. In this test, the child is asked, "Which room did we go into first (or next)?" then "Who was hiding there?" and "Where did we hide him?" The answers to these questions allow us to assess children's verbal memory of the what (e.g., Eeyore), where (e.g., behind the curtain in the bedroom), and when (e.g., the last room entered) of each hiding event. Once the child has answered all of the questions on the verbal recall test or indicates that he or she can recall no more, the nonverbal recall test is administered. In the nonverbal recall test, the experimenter asks the child to show the experimenter the room that they went to first (or next) and to retrieve the toy in each room.

In this modified version of the hide-and-seek task, 4-year-old children verbally recalled significantly more information about the what (i.e., toy), where (i.e., room and specific location), and when (i.e., order of room visit) of the hiding event than did 3-year-old children. In contrast, on the nonverbal test, the 3-year-olds recalled as much information as the 4-year-olds regarding where the toys were hidden. In fact, their nonverbal memory for information about both the room and the specific location within that room (e.g., under the bed) was almost at ceiling and exceeded their verbal memory for the same information by almost a factor of 2. In contrast, 3-year-olds still struggled, even on the nonverbal test, to accurately indicate when they visited each room; 4-year-olds were significantly more accurate at recalling the when information than the 3-year-olds. (We did not test children's recall of the *what* information on the nonverbal test because children are not able to express their memory for the toy behaviorally.)

Taken together, while the findings from the verbal test, on its own, suggest that 3-year-olds experience great difficulty in remembering the what, where, and when of the hiding event, the findings from the nonverbal test indicate that 3-year-olds do have a robust memory of the where information. Relying on verbal tests alone underestimated the amount of information they retained. Furthermore, our findings suggest that the key difference between 3- and 4-year-olds' memory of this particular event may, more specifically, be their ability to remember the temporal sequence of when each object was hidden (Hayne and Imuta, 2011). This finding supports the notion that, of the three W's of event memory, the temporal aspect of the event may be the most difficult to recall (e.g., Clayton et al., 2003; Suddendorf and Corballis, 2007; Tulving, 2005). By blending verbal and nonverbal tests, the hide-and-seek task allows us to gain a better insight into the similarities and differences in children's memory of events (defined by the three W's) between 3 and 4 years of age and underscores the fact that, even once they begin to talk, children may continue to rely heavily on nonverbal forms of representation.

Magic Shrinking Machine

The magic shrinking machine is a task that can be mastered by 2-year-olds, yet it is still fascinating and challenging for 4-year-olds (Simcock and Hayne, 2002, 2003). In this task, children insert large objects into the machine and, by performing a series of actions, create smaller but otherwise identical versions of the same object. In order to make the machine 'work,' children turn on the machine by pulling a lever to activate the lights on the front panel. They then place an object (e.g., a teddy bear) into an opening at the top and turn a handle on the side. Turning the handle produces a series of unique sounds. Once the sounds stop, the child can retrieve an identical but 'shrunken' toy from a door on the front of the machine.

In one of the original experiments with the magic shrinking machine, 2- to 4-year-old children were visited in their homes and were shown how to operate the machine (Simcock and Hayne, 2003). During this visit, the child's caregiver completed the MacArthur Communicative Development Inventory: Words and Sentences (CDI) and a checklist of words that were specifically associated with the magic shrinking machine event (e.g., 'handle' and 'ball'). The following day, the experimenters returned to the child's home to test the child's memory of the magic shrinking machine event. During the test, children's memory was assessed using verbal free recall, nonverbal photograph identification, and behavioral reenactment tests.

Although children's verbal recall increased as a function of age, it lagged considerably behind both their nonverbal memory and their general verbal skills. During the verbal interview, children failed to report aspects of the event that they clearly remembered on the basis of their nonverbal memory performance, even though they had the relevant words in their vocabulary. For example, 24-, 27-, and 30-month-olds reported almost nothing during the verbal interview, yet they could, depending on their age, accurately identify 2–6 of the target photos (maximum = 8) and reproduced 2–4 of the target actions (maximum = 5). Children older than 33 months of age generally had most of the 22 target words as part of their vocabulary, and they approached ceiling on the nonverbal memory measures; however, their verbal reports were still extremely lean, and they reported less than half of what they could have reported based on their productive vocabulary alone (Simcock and Hayne, 2003). Again, these findings underscore the fact that, even as fluent language speakers, young children still rely extensively on nonverbal forms of representation.

The Long-Term Fate of Preverbal Memories

The research reviewed thus far has clearly shown that children's ability to use language in the service of memory lags considerably behind their ability to use language to discuss the here and now. Thus, if we rely exclusively on what children can tell us about past events, we are likely to underestimate what they actually remember. In contrast, children's nonverbal memory skills emerge very early in development (for a review, see Hayne, 2004) and continue to exceed their verbal memory skills at least through early childhood (and possibly beyond). What happens to these early nonverbal representations over time? Do they disappear as children make the final switch to a primarily verbal coding format, or are some of these memories retained and translated into language over time?

In an initial attempt to answer these questions, Simcock and Hayne (2002), tested independent groups of 27-, 33-, and 39-month-old children for their memories of the magic shrinking machine event after a 6-month or 1-year delay. In that study, children took part in two demonstration sessions that took place on two consecutive days. The procedure for each demonstration session and for the test session was identical to that used by Simcock and Hayne (2003). Consistent with the data obtained when children were tested after a 24-h delay (Simcock and Hayne, 2003), children's performance on the verbal recall test lagged behind their performance on the two nonverbal tests when they were tested after a 6-month or 1-year delay. Even after the long delays, children, on average, demonstrated robust nonverbal memory of the magic shrinking machine event, recalling over 60% of the information on the behavioral reenactment test and 50% on the photograph identification test. In contrast, they reported only about 20% of the information during the verbal recall test. Most importantly, even though all of the children had acquired the majority of the target words as part of their productive vocabulary by the time of the 6-month and 1-year interviews, there was not a single instance in which their verbal reports of the event contained a target word that had not been part of their productive vocabulary at the time of encoding. That is, the children in Simcock and Hayne's (2002) study failed to translate their preverbal memories into language – instead preserving those memories in their original preverbal format.

Evidence of Verbal Translation of Preverbal Memories

Although Simcock and Hayne (2002) found no evidence for the translation of memories into language, there is at least some anecdotal evidence that such translation occurs. For example, when older children and adults are asked to recall their earliest personal memory, a handful report events that occurred around or before their second birthday (e.g., Eacott and Crawley, 1998; Jack and Hayne, 2007; Jack et al., 2009; MacDonald et al., 2000; Tustin and Hayne, 2010). In light of Simcock and Hayne's (2002) findings, what are we to make of these reports? On the one hand, given their retrospective nature, it is entirely possible that these very early accounts are not reliable – the events may have not taken place, or the participants may be relying on what they have been told about the event rather than what they actually remember on the basis of firsthand experience. On the other hand, given the frequency with which these early accounts occur in the literature, it is possible that a small handful of preverbal experiences have been retained over time and have been translated into language in such a way that they can be reported during an interview years, or even decades, later. If this is the case, how might it occur?

In addition to the magic shrinking machine event, the magic bubble machine task is another blended memory procedure that was developed by Morris and Baker-Ward (2007) to explore the translation of preverbal memories into language over a relatively brief developmental period. In the Morris and Baker-Ward (2007) study, 2-year-old children were first tested for their receptive and productive vocabulary for six basic colors; children's color knowledge was also assessed using teacher and parent reports. The following day, children took part in the magic bubble machine event during which they learned that one of the six colors of bubble soap (i.e., the target color) activated the machine, producing bubbles. In the 8 weeks following this event, an experimenter visited the children's classrooms for approximately an hour each week and conducted color-learning activities. After the 8-week color training, children were tested again for their knowledge of the six color words. At this time, children were also assessed for their memory of the magic bubble machine event using verbal recall, nonverbal color identification of the target color on a color chart, and behavioral reenactment in which children demonstrated how to activate the bubble machine.

Using this procedure, Morris and Baker-Ward (2007) found that 9 of the 31 children (i.e., ~30%) who did not know the target color word prior to the magic bubble machine event, but who subsequently acquired the word during the 8-week training period, used the target color word to describe the event during the verbal recall test. In other words, these children presumably encoded the target color without the benefit of language, maintained the memory over the 8-week

delay, and then mapped the newly learned word onto their earlier, preverbal representation. In contrast to the earlier findings reported by Simcock and Hayne (2002) and Morris and Baker-Ward's (2007) findings suggest that children might be able to translate a preverbal memory into words.

It is important to note that there were a number of procedural differences between the Simcock and Hayne (2002) and Morris and Baker-Ward (2007) studies, including the complexity of the events, the context in which the events took place, the length of the retention interval, and the addition of specific language training. One or all of these factors may have contributed to the difference in results. For example, the timing of the language training and the fact that it occurred in the same context as the original event may have facilitated children's ability to map a newly learned word onto a previously established representation. Whether similar translation would occur under more real-world learning conditions is not known, but it is a fruitful area for further research.

In addition to the high level of contextual support during the language-training portion of the study, the 2-year-olds in the Morris and Baker-Ward (2007) study were tested for verbal recall in the presence of the bubble machine (i.e., a highly salient retrieval cue), whereas in Simcock and Hayne's (2002) study, the magic shrinking machine was not present during verbal recall. The critical role of reminder object cues for young children's verbal recall has been demonstrated in previous studies (e.g., Bauer et al., 1995, 2004) and, therefore, suggests that the level of contextual support at the time of test may be another key determinant of whether children can access their preverbal memories via language (Morris and Baker-Ward, 2007).

Although Simcock and Hayne (2002) found no evidence of children using target words that were not part of their vocabulary at the time of the magic shrinking machine event to describe the event after a 6-month or 1-year delay, Jack et al. (2012) recently found some evidence in support of verbal translation of preverbal memories after a 6-year delay. In their study, 27- to 51-month-old children experienced the magic shrinking machine event and then were tested after 24-h and 6-year delays. Following the 6-year delay, 9 of the 46 children who took part in this study (i.e., 20%) were able to verbally report information about the event. Importantly, of these nine children, two described the event using a target word that was not part of their vocabulary at the time of original encoding.

So what set apart the children who were able to provide verbal report after a 6-year delay and those who did not? The nine children who were able to verbally recall the magic shrinking machine event had not performed any better during the 24-h interview than did the children who did not verbally recall the event at the 6-year interview. Furthermore, children's vocabulary skills and general memory skills at the times of encoding and test were not related to their long-term verbal recall performance. Jack et al. (2012) did find, however, that the few children who were able to provide verbal reports of the magic shrinking machine event after a 6-year delay were the ones who had actively participated in conversations about the event with their parents during the retention interval.

The importance of mother–child conversations on children's early memory development is now well established. A large body of research has shown that mother–child conversations about the past influence children's ability to develop well-organized and elaborate memory narratives (Dunn et al., 1987; Eisenberg, 1985; Farrant and Reese, 2000; Fivush, 1991; Fivush and Fromhoff, 1988; Haden et al., 2009; Harley and Reese, 1999; Hudson, 1990; Newcombe and Reese, 2004; Peterson and McCabe, 1992, 1994; Reese, 2002). Jack et al.'s (2012) finding extends this literature by suggesting that the opportunity for children to verbally rehearse their memories may play an essential role in their subsequent ability to translate their preverbal memories into language. Similarly, it is also possible not only that the language training in the Morris and Baker-Ward (2007) study with the magic bubble machine may have helped children to learn the relevant color word, but also that the training per se may have provided a rehearsal opportunity for the target event, keeping the memory active over the retention interval and providing the opportunity for the translation to occur. This possibility remains to be tested.

Verbal Reminders

There is a well-established literature with human infants showing that even after a nonverbal memory has been forgotten, the memory can be reactivated and expressed given the appropriate retrieval cues (e.g., Butler and Rovee-Collier, 1989; Herbert and Hayne, 2000; Rovee-Collier et al., 1980, 1985). Although the nature of an appropriate retrieval cue is initially quite specific to the conditions of original encoding, as a function of both age and experience, the nature of these cues gradually broadens (Hayne, 2006). Over the course of development, the nature of effective retrieval cues gradually broadens to such a degree that language cues also become effective retrieval aids – potentially even for memories that were originally preverbal or nonverbal in nature. We have recently found evidence that suggests that verbal reminders of past events may be a key to the maintenance of early memories, even before children have the full-fledged language skills to verbally rehearse and retrieve memories on their own. In particular, for preverbal and early-verbal children, exposure to simple questions such as "Do you remember when…?" may help maintain a preverbal representation long enough that they can use their emerging language skills to translate the memory into words.

As an initial attempt to investigate the age at which children begin to exploit simple verbal reminder questions, we tested 2-, 3-, and 4-year-olds on the VPC paradigm and measured their retention of a visual stimulus with or without a verbal reminder (Imuta et al., 2012). In this study, we first familiarized children with a three-dimensional cartoon face, and, following a predetermined delay, we tested children's memory of the visual stimulus by presenting them with the familiar face and a novel face, side by side, and coded for children's looking behavior. To investigate the effect of simple verbal reminder questions on children's memory retrieval, immediately prior to the testing session, children in the verbal reminder condition were asked, "Can you remember coming

here a little while ago?" followed by "Can you remember what face you saw the last time you came?" Children in the control conditions were either simply complimented on their clothing or asked an unrelated question about their favorite toy. Using this procedure, we found that children in the control conditions did not exhibit retention of the visual stimulus after a delay. In contrast, we found that 2-, 3-, and 4-year-olds who were provided the verbal reminder questions exhibited excellent retention (Imuta et al., 2012). The finding that children as young as 2 years of age can exploit simple verbal reminder questions to retrieve a nonverbal memory suggests that this kind of reminding may play a crucial role in allowing these preverbal memories to be translated into language over time.

Beyond the Preverbal-to-Verbal Transition

Although we have largely focused on the fate of preverbal memories, it is important to note that even our early *verbal* memories are rarely recalled in adulthood (Tustin and Hayne, 2010). Indeed, the general absence of memories from early childhood was noted by Freud (1963), who coined the term 'childhood amnesia' (or 'infantile amnesia') to describe the phenomenon. Since Freud (1963), a number of theories have emerged, and, with few exceptions, these theories have largely focused on *human* developmental transitions such as the preverbal-to-verbal transition that we have discussed here and elsewhere (Simcock and Hayne, 2002), the emergence of a sense of self (Howe and Courage, 1993), and the emergence of episodic memory (Wheeler et al., 1997), to name a few. Interestingly, work with nonhuman animals has demonstrated that they too experience 'childhood' amnesia (Callaghan and Richardson, 2012), suggesting that theories that focus solely on *human* developmental transitions cannot provide a complete explanation of the phenomenon.

Importantly, work with nonhuman animals underscores what Hayne and Jack (2011) referred to as the 'forgotten explanation' of childhood amnesia, that is, forgetting (Frankland et al., 2013; Josselyn and Frankland, 2012). The role of forgetting in childhood amnesia is often ignored because normal forgetting functions cannot explain the specificity and degree of amnesia that adults display (Wetzler and Sweeney, 1986). With respect to specificity, Tustin and Hayne (2010) have demonstrated that forgetting occurs across a protracted, rather than specific, developmental time frame. They found that as the age of participants increased, so did the age of their earliest memories, such that younger participants had significantly earlier memories than older participants (Tustin and Hayne, 2010). With respect to the degree of amnesia, recent nonhuman animal work has demonstrated that childhood amnesia coincides with a period of high neurogenesis in the hippocampus (Frankland et al., 2013; Josselyn and Frankland, 2012), providing an explicit neural mechanism for the steeper forgetting functions that we commonly see early in development in humans and other animals. That is, the high neuronal turnover in the hippocampus that occurs early in development impairs the ability to recreate the specific patterns of activation that are required to recall specific memories (Guskjolen et al., 2013).

Conclusions

In conclusion, the data reviewed here show that children continue to rely on their nonverbal memory skills over a protracted period of development. If we only ask them questions about what they remember, we are likely to underestimate the content of their memory. Although most of these early, nonverbal memories will ultimately be forgotten, there is some evidence that at least some of them are retained over significant periods of development. Although rare, it may also be possible that at least a small handful of these memories might be translated into language. We conclude that the probability that translation will occur may be dependent, at least in part, on the availability of verbal reminders during the retention interval. The fate of these early preverbal memories may provide yet another key to the intriguing phenomenon of childhood amnesia.

Children and Families in Social Work

Nick Frost, Leeds Metropolitan University, Leeds, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article explores social work with children in families. Different levels and forms of social work practice are explored. It is argued that such practice exists at the complex interface of the state and the family, and that this makes such work inherently complex and contested. The article concludes by considering the importance of professional judgment and what the future of such work may look like.

Introduction

Social workers across the world work with children and their families to promote the perceived best interests of the child. Social workers operate at the interface of the state and the family: an interface that is often contested and controversial. Their work, particularly when concerned with child maltreatment, is often subject to high levels of public, political, and media scrutiny (Nelson, 1986; Parton, 2006).

This article will explore how social work with children across the world has many common features: the core of the work shares approaches such as developing a positive relationship with the child, and where possible their parent(s), while empowering and protecting children and young people. But there are also differences in social work practice dependent on the social and political context in which it is situated.

This article will argue that social work can be understood at three key levels: the social structural level, the community level, and the family/individual level. It will also be argued that social work with children and families consists of a number of core practices: family support, safeguarding and the provision of alternative care, and permanent placements for children. This article will conclude with a discussion of professional judgment and development before speculating how social work practice with children may look in the future.

The objectives of what follows are to

- analyze different levels of social work practice with children and families;
- explore differing forms of practice with children and their families;
- reflect upon professional judgment and development; and
- suggest future policy and practice framework for working with children.

Underpinning Levels and Approaches to Social Work with Children and Families

When social workers work with a child it is usually because the child is facing some sort of problem or challenge. A child living with a consistent and loving parent, in a materially and emotionally comfortable environment, is unlikely to ever come across a social worker. Rather social workers practice with children who may be abused, neglected, abandoned, or deprived. Within social work there are many ways of understanding the many challenges that a child might face: how professional social workers conceptualize the challenges facing the child will have a profound impact on how they choose to intervene. We can understand children's problems in a number of ways as demonstrated in Table 1.

While Table 1 is useful in helping us understand different styles and approaches to social work, in reality many social workers will utilize combinations of different models and interventions, depending on the organizational framework they operate within and the specific child they are working with. Often workers will combine styles of working – moving from being a therapist, to an advocate, to a campaigner, for example. In this sense, social work occupies a particular flexible space – in contrast to the more defined role of a lawyer or doctor, for example.

Social work is a responsive role which has to be fluid and flexible to achieve its goal – that of promoting the best interests of the child. As we will see later this gives social workers a particular role in the multidisciplinary professional 'team around the child' (Anning et al., 2010).

Levels of Intervention

Structural and Political Interventions

The most global and overarching forms of addressing the challenges of childhood exist at the political and social structural level (Frost, 2011). Social workers all over the

Table 1 Understanding childhood challenges

Theory/level	*Explanatory framework*	*Interventions*
Social structural/ political	Childhood problems are situated in deep-seated social injustice and inequalities	Political/campaigning initiatives
Community/ ecological approaches	Community, family, and individual factors combine to produce challenges for children	Combination of methods ranging from political and community initiatives
Family systems/ Individual approaches	Childhood problems are rooted in household interactions	Therapy Family casework Family support

world will be engaged in such styles of work: it may involve campaigning for change; gathering data that demonstrates the nature of childhood disadvantage; and/or mobilizing adults or children themselves to bring about change. Social work as a profession needs to reflect upon how effective it is in tackling major social problems such as domestic violence, rape, and genital mutilation. This form of action has long historical antecedents going back to the origins of social work and Victorian figures such as Octavia Hill and the founders of the large childhood charities such as the Societies for the Prevention of Cruelty to Children (Ferguson, 2004). Often the Victorian philanthropists would combine the levels explored in **Table 1** – they would campaign for social change, work in communities, and practice with individual children and their families.

Today, social workers are working for such change through global organizations such as UNICEF or in NGOs such as Save the Children. While the Victorian pioneers often worked as if they somehow knew 'the best interests of the child,' most organizations aim to give a voice to children by enhancing their participation in both the policy and practice areas in a manner consistent with the United Nations Convention on the Rights of Children (www.unicef.org.uk accessed 05.06.13).

The campaigning and collective role of social work sometimes positions it in a vulnerable position. Social workers are often described as being overly 'politically correct,' 'revolutionaries,' or alternatively 'wimps' and 'bullies' (Franklin and Parton, 2001). These accusations reflect, to return to one of the earlier themes, the complex relationship between the state and the family. The social worker can be accused of 'intervening too much,' when removing children from their birth parents, or 'intervening too little,' when a child dies at the hands of a parent. Particular children, such as the child known as 'Baby Peter' in England, often attract high levels of media and political attention (Laming, 2009). This complex tension forces social workers to walk a 'tight wire,' which is sure to be both controversial and contested.

This 'tight wire' leads to social work existing in a complex relationship with the media, politicians, and public opinion. In the United Kingdom, for example, ever since the late 1960s, social work has been subject to sustained public, media, and political criticism. During the same period, social work has been invested in by government, grown both in terms of numbers and professional status, and been granted an increasing number of statutory responsibilities. This we might identify as something of a paradox: the more social work is seen as failing and controversial, then the more it has to be supported and invested in. Alongside this investment, particularly in the Western world comes increased monitoring and inspection by the state and its agencies (Frost and Parton, 2009).

The political explanations of this paradox are complex and at times contradictory: the explanations exist somewhere along the 'welfare'/'social control' continuum. Modern liberal governments are obliged to invest in childhood: to utilize an overused cliché, 'children are our future,' and their welfare must be sustained. Thus, any social system that wishes to reproduce itself (in both the political and biological senses) has to invest in childhood. In liberal and social democratic societies the family will play the major role in nurturing childhood: with varying degrees of state support. The social work role emerges when the family is perceived as failing in this nurturing role (Donzelot, 1979). Social work will therefore intervene with the abused child, the neglected child, the child not attending education, and so on. The social worker is therefore simultaneously both a supporter of the vulnerable child and the enforcer of the authority of the state. Different commentators vary in their weighting of these roles. Some see the social worker as a champion of children's welfare, some perceive them as the enforcer of the authoritarian state and yet others as a complex combination of the two. Few ask how the child might view the social worker.

Social workers will vary in their approach to the family–state interface. Some will perceive themselves as 'radical' (Bailey and Brake, 1975; Bolger et al., 1979) or 'feminist' (Dominelli and McLeod, 1989) social workers pursuing overtly political approaches to their work and toward social change, others will focus on a strongly individualized agenda of therapy (Payne, 2005).

Community-Based Interventions

The global and political initiatives outlined above often take a concrete form of locally based and delivered initiatives. These range from major health or nutrition-based projects in countries facing shortages and absolute poverty, to community play schemes or parenting support in industrial and postindustrial countries. The underlying theory is the same as those working at the political level and shares a political element that is we cannot address childhood inequalities solely through work with individuals, and therefore broader-based interventions are required (Lavelette, 2011).

Community-based schemes vary considerably. They may include area-based antipoverty schemes, community work schemes encouraging collective campaigning and organizing, or campaigns against domestic violence or substance abuse. Social workers will normally be working in these contexts alongside community development workers, education workers, health professionals, and many others. The social worker may bring their specific skills in relationship building, professional liaison, and child-centered welfare work (Brennan et al., 2013).

Such initiatives are often seen as 'preventive.' They are a form of social intervention that is often universal in intent, that is, available without stigma to all sections of the population. This idea of prevention is central to social work. The initial ambition of many social workers will have been to work in prevention, which is sometimes conceptualized as 'family support' or 'early intervention.' The theory is that by offering support before social problems have become embedded the social worker can contribute to the prevention of later problems such as youth crime, child maltreatment, or family breakdown. Family support, often related to younger children, can also occur in the form of early help with older young people, early in the emergence of a particular problem or challenge. Contrary to popular perceptions, the social worker value-base is strong in relation to family support, and usually social workers regard the removal of the child to care as a last

resort. Prevention sits at the heart of child and family social work (Frost and Dolan, 2012).

Family-Based Initiatives

Family support may exist at both the levels explored so far: the political level and the community level. Fundamentally, however, it is an activity that exists at the level of the household (Georgas et al., 2006). The social worker may offer a 'personalized' combination of counseling, therapeutic interventions, practical help, and services. Usually this will involve cooperation with other professionals – in health, education, and related services. The role of the social worker may be involved in the assessment of a social situation – often using an ecological approach which takes into account the individual, the family, and community settings and their interplay (Jack, 1997). Having undertaken an assessment, social workers may play the role of 'broker' or 'case manager' – planning a coherent package of support in partnership with the family. They may provide direct support services – building relationships with the child and their parent(s) (Folgheraiter, 2003). Many social workers in modern industrialized societies report that they are no longer able to play this role – and that their work has become dominated by the protection of maltreated children. This will often involve rapid assessments and finely judged interventions – the practice safeguarding of children is examined below (Ferguson, 2011).

Forms of Social Work Practice

Social work with children and their families can take many forms. It is argued here that social work can be understood as comprising of four major practices: family support, safeguarding, provision of alternative care, and the provision of permanent alternatives.

Supporting Families

Family support work involves assisting families to raise their own children and is often linked to reducing the need to bring children into state care. Within family support practice there are a range of approaches often theorized as being at primary, secondary, and tertiary levels (Frost and Dolan, 2012). Primary prevention can operate at the social structural level, which we have explored earlier. It may also involve initiatives involving universal provisions such as play schemes, drop-in centers, and welfare advice. At the secondary level, family support practice is more focused on families that face specific challenges – for example, parents might be lonely, isolated, or depressed. The international organization Home Start provides an example of intervention at this level by providing professionally supported volunteer home visiting to families with identified needs. At tertiary level, interventions are focused at more severe social problems and a smaller number of families: perhaps involving domestic violence, substance abuse, or parenting problems.

Family support is a 'slippery concept,' which is difficult to define (Frost and Dolan, 2012). While social workers are involved in family support, it involves other professionals – such as day care, health, and play workers – and covers five core ideas.

- First, family support is based in the idea of identifying problems early, and assumes that it is better to offer support early in the life of a problem, before it becomes entrenched and difficult to resolve. For example, if a parent has problems communicating with a child it is better to provide advice and support when this emerges as an issue, before conflict arises between the child and parent.
- Second, family support is proactive. It attempts to work with children and their parents, and aims to bring about positive change for the child and the family.
- Third, family support implies partnership. It cannot be imposed on a family. This demands particular skills and approaches from the professional involved.
- Fourth, family support is based in a theory of change. It assumes that positive change can be brought about through family support initiatives and that social work has a key role to play within this change.
- Finally, family support is seen as bringing about wider social benefits through the prevention of social problems such as youth crime and child abuse.

Protecting Children

It is the protection of children that is the highest profile activity that social workers are involved in. In many parts of the globe this has been associated with 'scandals' where social work practice has been blamed for intervening too little or too late, or sometimes for intervening too much. Safeguarding children is very challenging for social workers – basically it involves attempting to assess whether the child's best interests are served by remaining with their birth families or being removed to substitute carers either on a short-term or long-term basis.

Our understanding of child abuse is constantly evolving and changing. For example, since the end of the Second World War we have seen the emergence of 'the battered baby syndrome,' child sexual abuse, institutional abuse, Internet abuse, and most recently we have a growing understanding of the organized sexual exploitation of young people through group and gang grooming. We can see that our understanding of child abuse is 'socially constructed': ever changing and changing across time and space. These understandings are a shared professional process but social work has played a key role in our understanding of the changing nature of child abuse (Parton, 2006).

The complex nature of the social work task is hinted at in the previous paragraph: how can we respond to ever-changing phenomena? The uncovering of then newly articulated forms of abuse could be accompanied by denial: 'battered babies,' (Parton, 2006) incest and ritual forms of abuse have all been accompanied by strenuous denial (Nelson, 1986). Awareness of the damage of more long-term subtle abuse has also been vital to the timing of interventions, for example, in cases of emotional abuse and long-term neglect. New forms of proactive practice have to evolve to detect abuse and to protect children. Social workers, and associated academics, are often in the forefront of campaigning and practice developments in this field.

Good practice is focused on listening to children, providing healing for any trauma they have suffered and in providing safe and sustainable care for them. This takes us to a discussion of the provision of alternative care for separated children.

Alternative Care

In most social systems where children cannot live with their birth parent(s), social workers are involved in finding alternative forms of care for them: this may be in the form of institutional care, kinship care, foster care with strangers, or adoption. The deployment and legal base of these alternatives varies across the world. In some countries, kinship care predominates (e.g., Spain), in others, large residential provision exists (e.g., India), and in yet others, foster care with strangers dominates (e.g., United Kingdom) (see Lerch and Stein, 2010).

The provision of alternative care for separated children is a core social work activity where the social work authority is 'in loco parentis' (Hannon et al., 2010) and has clear and unequivocal responsibility for the child. In many ways this is an 'acid test' for the social work profession: can it provide positive outcomes for children in care?

There is some positive and suggestive evidence in relation to children in alternative care. Popular discourse is often that outcomes for children in care are poor. This discourse tends to underplay the poorer starting points for children who enter the care system: it is more valuable to measure the 'value-added' by the care system. More realistically there are probably three groups: children who have stable care careers who are often successful when they move on; a middle group who can be successful if adequately supported; and finally a group, often with troubled pasts and disrupted care careers who may well struggle once having left care. Stein refers to these groups as 'moving on,' 'survivors,' and 'strugglers' (Stein, 2012). Judgment on the care system, therefore, has to be more nuanced than that it is 'failing children' and social workers need to recognize the differing needs of the three groups. All three will require some support with a mentoring role more useful for the 'moving on' group, more targeted support for the 'survivors' particularly when they face transitions, and intensive, outreach, and crisis support provided for the 'strugglers' group.

Of all areas of social work, the research evidence in field of children in care and leaving care is probably the strongest. The evidence strongly suggests that good quality care, provided in stable placements, with a gradual and supported transition to adulthood can provide successful outcomes for children in care (Stein, 2012). It also needs to identify and strengthen resilience factors in children – those factors that enable them to survive childhood adversity (Rutter, 1990).

Permanence

Most countries have a form of adoption: the permanent transfer of parental rights and responsibilities to someone other than the birth parent. Adoption is therefore a form of 'permanence': aiming to provide stable and ongoing care for children separated from their birth parents. Adoption acts as a route out of the care system or as an alternative to the system where children are adopted from birth. In most jurisdictions, the social worker has a key role in the adoption process: it remains an important social work role (Javier et al., 2007).

As with other aspects of social work adoption is a publicly high profile and controversial form of child welfare practice. Each aspect of the adoption process is complex and involves subtle elements of professional judgment. Let us examine some of these complexities in turn and assess how they can be addressed.

When should children be placed for adoption? The removal of children from their birth parent(s) remains one of the most demanding arenas of social work practice. Sometimes the birth parent(s) requests adoption for their child, and in some cultures this may be arranged informally. In more legally regulated states, frequently the social worker removes the child utilizing the powers available to the family court. In the context of international adoption, issues of poverty and inequality are strongly at play (Repo and Yrola, 2011). The birth parent will usually be angry and uncooperative, certainly at the time of removal and during court proceedings. Sometimes a child will be removed at birth – especially where the mother has been abusing substances during pregnancy or when she has had previous children removed: this is clearly a highly emotionally charged and demanding process (Javier et al., 2007). In other situations, the child may be removed after a period of abuse and neglect. Here, the social worker, usually with the assistance of the court and other professionals, is exercising complex professional judgment. The parent(s) who have had children removed will normally have been offered a package of family support before any decision to remove the child is made. This will vary considerably depending on the social and political contexts that the social worker is operating within. Decisions about when the support package should be withdrawn and the child removed, and how many packages of support should be offered, remain among the most challenging decisions within the social work lexicon. It is unsurprising that social work practice is often open to challenge – for intervening either 'too early' or 'too late.'

Having explored when children should be placed for adoption, who should be approved as adopters is explored next. The assessment of adopters by social workers is a further area of complexity. Should prospective adopters be rejected for smoking too much, eating too much, being too old, or too culturally insensitive as the popular press often reports? Further complications exist: should gay and lesbian people be enabled to adopt, for example? (Gates et al., 2007). Should people of 'extreme' political views be able to adopt? In the case of well-publicized 'celebrity' adoption wealth and fame also seem able to influence the adoption process (Repo and Yrola, 2011). All these examples have been subject to recent controversies and are likely to continue into the future as these issues lay at the heart of belief systems about the family, parenting, and childhood.

There are perhaps two helpful frameworks for addressing these dilemmas: but of course there are no easy answers. First of all, it is helpful to see adoption as a service for children, not for adults. Thus, the measure should not be what is good for adults but what is in the 'best interests of the child.' The concept of 'best interests' is contested and raises many issues about the child's active participation and to what degree adults can decide what is in the child's 'best interests.' Secondly, potentially

successful adopters should be carefully and professionally assessed for their ability to address the needs of a child. Thus, it is important that adopters are assessed for their caring skills and that they are not discriminated against on grounds of gender, class, and sexuality, for example (Javier et al., 2007).

How should children and adopters be matched? Here we find further controversial decisions that social workers have to address through their practice. Perhaps the fundamental question is around transracial adoption: can adopters effectively care for a child from a different ethnicity? In practice, this issue usually revolves around whether white carers can care for children of color (Lee, 2003). This is perhaps the most controversial and contested issue in social work practice and has generated a considerable literature and campaigns, both for and against transracial adoption (Kirton, 2000). The research evidence here is contradictory. Some researchers argue that transracial placements can provide positive placements with good outcomes (Harris, 2006), while other research points to a lack of self-esteem and confused racial identities resulting from transracial placements (Gaber and Aldridge, 1994). The issue has been subject to political campaigns and strong opinions on both side of the debate particularly when taking children out of their country of origin into more Western environments (Repo and Yrola, 2011). Professionally social workers have been inclined to emphasize the need for sensitive ethnic matching – arguing that this encourages children to grow up with positive self-esteem and the ability to handle racism and prejudice later in life (Kirton, 2000).

What support should be offered postadoption? If adoption is permanent and provides a 'normalized' placement for children, how should social workers view postadoption support? What permanence means to adopters and traumatized children often has a very different meaning to social workers. The term 'forever mummy or daddy' means little to a child whose life has no concept of forever and to an adopter when marriages or partnerships break up or difficulties remain unsupported. Here, we have seen a revolution in social work practice. In the post–Second World War environment adoption was a 'closed' process – a service for orphans or the stigmatized children born 'out of wedlock' (Luckock, 2008). Many of the children were healthy babies and were brought up as if they were the birth children of their adoptive parents. The logic of this approach to permanence was that little or no support was offered to adoptive parents. But in recent decades, adoption has changed. There are fewer 'healthy white babies' to adopt and the service is now provided for older children, who may have had traumatic childhoods or who may be disabled or from a minority ethnic group. Good adoption practice is now 'open,' which means that children and young people know that they are adopted and have life story books utilized to help them understand their past and why they were adopted. Recognizing the challenges and openness of contemporary adoption, it has followed that postadoption support can be provided and this can help reduce the tragedy of adoption placement breakdown. However support in this area remains underdeveloped in many parts of the world. The idea that children have been 'rescued' from previous 'damaged' families and placed in a 'better' family has fed into ideas of them then having to be independent. In recent years, however, adoption support has been gaining support (Luckock, 2008).

Professional Judgment

Social work with children and families involves taking delicate and nuanced decisions about how the state and its agents should relate to children and families. For this reason, social work is often controversial. Good social work practice needs to make sure that practice is grounded in opportunities for critical reflection on both the process and outcomes of social work. In order to promote effective social work, the profession requires:

- An educated and trained workforce, including high level continuing professional development.
- A workforce that is supported and encouraged in the complex roles that it undertakes.
- A workforce that has opportunities for high quality professional supervision that supports critical reflection.
- A workforce that can access a range of high quality services to support the work it undertakes.
- Political and social systems that recognize and support the development of the social work role.

We also need to recognize the challenging nature of social work decision making and the risks involved in such complex work. Harry Ferguson in his body of work reflects well on the complexities of the social work task and the number of complex microdecisions involved in the home visit, for example (Ferguson, 2011).

Social work also needs to evolve as a profession. There are tensions between the idea of professionalism – which traditionally may have implied forms of elitism and ensuring high material rewards – to a new form of professionalism that strives toward genuine participation by children and young people. Developing from the UN Convention on the Rights of the Child, social work since the latter quarter of the twentieth century has been increasingly embedded in the participation of children and young people. All over the world there are youth parliaments, forums, and 'children in care councils' that enable young people to have a real impact on services. The exact forms differ across the world: in India, working children have been organized (Reddy and Ratna, 2002); in England, a day where young people 'takeover' has been organized (http://www.childrenscommissioner.gov.uk/takeover_day, accessed 05.06.13). This participation is an unfinished process and attempts to develop genuine partnership and participation need to be at the center of contemporary forms of professionalism (Cree and Davis, 2007).

This article has focused on social work, but in an increasingly complex and networked society, intractable social problems are not amenable to 'single profession' solutions (Anning et al., 2010). Many social workers are now embedded in multiprofessional settings – such as hospitals, children's centers, or youth crime teams. This enables professionals to share information, skills, and ideas in order to build more flexible, holistic, and responsive approaches, by working through 'the team around the child.'

A Future of Social Work with Children and Families

Social work with children and families has changed and evolved over time, varying according to the social context in which it operates. While it is difficult to predict future trends

and patterns, I can speculate on some future challenges that social work is likely to face. Multidisciplinary approaches seem to be one future direction that is becoming increasingly embedded in the profession and that social work needs to promote more deeply rooted forms of participation.

Technological advances have led to new challenges for safeguarding. The Internet allows perpetrators of abuse new forms of unprecedented global access to children. The mobile phone has equally underpinned new forms of organized and networked abuse that would have been more difficult for abusers before such technology existed. New safeguarding challenges are likely to emerge as technology evolves.

Many of the social problems discussed in this article have their roots in social inequalities and poverty. As much of the Western world suffers from 'austerity' and the economic crisis, it is probable that problems such as family breakdown and youth crime will become more widespread. Global developments such as conflict and displacement also tend to have an impact on children and young people – sometimes leaving them vulnerable to abuse or abandonment. Unaccompanied asylum seeking children are among the most vulnerable children and social work needs to be alert because such issues arise in a globalized and sometimes destabilized world. Social workers have an important, although not exclusive, role to play in relation to these social problems.

Conclusion

This article has outlined the complex, diverse, and challenging roles facing social workers in their professional practice with children and families. Specifically the following issues have been explored:

- the different levels of social work practice with children and families,
- differing forms of practice with children and their families,
- the role of professional judgment and development, and
- what future policy and practice may look like.

Fundamentally, it has been argued that social work exists at the interface between the state and the family and that this relationship is contested and controversial. For this reason, the social work profession requires both space for reflection and robust political support if it is to address its demanding and changing roles successfully in the best interest of children and young people.

Abstract

This article offers a broad survey of the multiple ways law governs children's lives. The legal regulation of children is neither a subset of family law nor a limited set of exceptions to the legal regulation of persons generally. Law instead creates a legal category of child and governs that category differently than it governs adults across many spheres, including the home, schools, child welfare systems, juvenile justice institutions, and the market. The article analyzes the justifications and effects of this legal approach, highlighting the ways law determine whether parents or state actors may exercise authority over children.

Law governs children's lives in multiple ways. Although parents generally make decisions on behalf of their children, law grants parents that authority. Law does so by recognizing parent–child relationships, granting and protecting parental rights, and specifying that children lack the legal capacity to make most decisions on their own. In some situations, however, law carves out exceptions to parental authority, substituting the state's judgment for that of parents. Law thereby more directly governs children's lives through compulsory education regimes, child protection systems, child labor restrictions, and laws responding to children's misconduct, among other means. In each of these ways, law specifies whether parents or state actors may exercise authority over children (Buss, 2004; Guggenheim, 2005). Debates continue about where to draw the line between parental and state authority (Rosenbury, 2007), but children remain subject to the decisions of either their parents or the state.

This legal framework responds to the fact that children are born completely dependent on adults and only over time develop the mental and physical capabilities needed to pursue more independent courses of action. Parents and the state therefore share the duty of caring for children as vulnerable individuals in need of protection, support, and guidance (Dailey, 2006). Yet law does more than reflect periods of reduced capacity due to chronological age. Law itself participates in the construction of childhood, most noticeably by specifying different ages for when children become legal adults for purposes of marriage, sexual activity, employment, driving, drinking, voting, and criminal prosecution, among other activities (Cunningham, 2006). Individuals therefore may be legal adults for some purposes and legal children for others.

These diverse legal definitions of childhood and adulthood at times reflect the relative nature of maturity, as individuals of a certain age may be mature enough to make decisions in some contexts but not others (Todres, 2012). At other times, however, law's shifting age cutoffs reflect political considerations other than, or in addition to, understandings of capacity and maturity. Moreover, some forms of children's incapacity are explicit consequences of law. Because law generally does not permit children to engage in wage labor, enter into enforceable contracts, or consent to medical care, for example, children are dependent on adults to perform those functions for them. In this respect, the age and maturity of children often does not matter; instead, the relevant factor is the legal status of 'child' attaching to the individual in question (Appell, 2013).

This article surveys the ways this legal treatment of children affects multiple spheres of children's lives. Specific legal regulation of children varies from jurisdiction to jurisdiction, but the general legal framework set forth above produces a baseline level of treatment that is remarkably consistent across jurisdictions. Such consistency remains even in jurisdictions that have embraced robust conceptions of children's rights, including those set forth in the United Nations Convention on the Rights of the Child, which has been adopted by every jurisdiction except the United States and Somalia (Bartholet, 2011; Guggenheim, 2006). The article concludes by briefly highlighting some of the strengths and weaknesses of law's general approach to children.

Law across Children's Lives

Law treats children differently from adults across a wide spectrum of substantive areas. The legal regulation of children is therefore neither a subset of family law nor a limited set of exceptions to the legal regulation of persons generally. Law instead affects children in many spheres, both inside and outside the family, including schools, child protection systems, juvenile justice institutions, and the market. This article will survey these diverse spheres by discussing children's relationships with caregivers, including the establishment of parental ties; children's protection from maltreatment; children's educational experiences, including access to quality education; children's experience in the juvenile justice and criminal law systems; children's interactions with the market and civic life, as workers, consumers, and citizens; and children's peer relationships.

Children's Relationships with Caregivers

Law recognizes the parent–child relationship and then bestows rights and obligations upon legal parents and, to a lesser extent, children. The parent–child relationship arises most commonly through (assumed) genetic ties, with birth certificates listing as legal parents the woman giving birth to a child and the man she identifies as the father. Legal parentage may also arise through

adoption, marital presumptions, gestational agreements, and, in limited circumstances, functional or *de facto* caregiving (Dwyer, 2006; Meyer, 2006). Generally, no more than two adults are recognized as the legal parents of a child. Accordingly, children may not have access to genetic parents who are not their legal parents, including sperm and egg donors, although open adoption is increasingly common (Blauwhof, 2009; Cahn, 2012).

In these ways, adults opt into the legal status of parent, through conduct or agreement. Children, in contrast, are born into the legal status of child or moved into it. Despite children's lack of agency in this respect, the United Nations Convention on the Rights of the Child declares that children have a right to be raised by their parents, as opposed to the state, and to have a relationship with both parents, even if the parents are separated. The United States has not ratified, accepted, or acceded to the Convention, in large part because of concerns that children's rights will threaten traditional lines of authority within the family. Children in the United States therefore do not possess an affirmative right to a parental relationship, although robust notions of family privacy generally dictate that children are raised by legal parents instead of the state (McClain, 2006; Meyer, 2000).

Once the state recognizes a parent–child relationship, it generally does not specify the content of that relationship beyond dictating that parents must provide their children with life necessities, including food, clothing, shelter, and medical care. In exchange for this financial support, legal parents are given broad authority to direct the upbringing of their children, imparting whatever values they please (Harris et al., 1990). For example, the United Nations Convention on the Rights of the Child specifies that parents have a right to control their children's religious, educational, and cultural heritage. The United States Supreme Court has also interpreted the Fourteenth Amendment of the United States Constitution to protect the fundamental right of parents to make decisions concerning the care, custody, and control of their children.

Parents therefore enjoy a right to direct the upbringing of their children largely free from state intervention. The state may intervene to determine custody arrangements and specify the details of financial support when children are born to unmarried legal parents or to legal parents who subsequently divorce. In such situations, judges enter custody and child support orders based on their views of the best interests of the child (Mnookin, 1975; Scott and Emery, 2013). If parents are not subject to such custody or child support orders, parents alone may determine where their children will reside, how they will interact with others, and how they will be financially supported. If children object to their parents' choices, they generally have no recourse in court unless the state believes their parents are defaulting in their duties, as discussed in more detail in the next section.

States may intervene in parent–child relationships, often against the wishes of parents and children, if parents require direct financial support from the state or otherwise are not performing their duties. In the United States, for example, parents receiving public assistance often must use the funds to support their children in certain ways and open their homes to social workers for inspection (Cahn, 1999). Some jurisdictions also affirmatively monitor children being raised by nonlegal parents, such as foster parents, at times disrupting relationships between children and foster parents in order to preserve the primacy of children's relationships with their legal parents until such relationships are terminated, as discussed in the next section.

Children thereby remain under the authority of their legal parents, subject to limited exceptions, until they reach the age of majority, usually 18 years of age, or are otherwise emancipated. Children under the age of majority may become emancipated by operation of law, most commonly when they marry or enlist in the military, or by petition. In order for emancipation petitions to be successful, children often must provide evidence that they are financially independent, able to manage their affairs and, in some jurisdictions, that emancipation would be in their best interests. These requirements make emancipation unavailable for most children. Moreover, some states in the United States rescind emancipation if an emancipated child subsequently becomes indigent.

Some children have attempted to 'divorce' their parents outside of the emancipation context, but they have generally failed. Even if not emancipated, children may direct their own medical care in some situations. As discussed in more detail below, many jurisdictions permit children to access reproductive health care and treatment for sexually transmitted diseases or drug abuse and alcoholism without parental notification or consent. Judges in most jurisdictions may also declare a child to be a 'mature minor' capable of directing medical care for certain purposes (Wadlington, 1994).

Children's Protection from Maltreatment

States most intensely intervene in parent–child relationships when parents are suspected of neglecting or abusing their children. Such intervention may take various forms, including mandated counseling and parenting classes, removal of children from the home, criminal prosecution, and the termination of parental rights. Race and class play a large role in this area of law. Poor families and families of racial and ethnic minorities may more likely experience state intervention and removal of children, often because of bias and the imposition of norms derived from majoritarian childrearing practices (Roberts, 2002). This differential treatment persists despite facially neutral laws and robust antidiscrimination norms and rights.

Jurisdictions define child maltreatment and govern the varied responses to it. When children are harmed by adults who are not their parents, jurisdictions generally invoke the criminal process. When children are harmed by their parents, jurisdictions often do not invoke the criminal process. Instead, most jurisdictions have developed separate, noncriminal child protection systems to respond to parents who are harming their children or otherwise endangering them. This noncriminal approach is thought to better protect children's welfare, as it directs state services to parents and children and often permits children to remain with their parents or to reunite with their parents more quickly than the criminal process would allow (Huntington, 2006).

Child protection systems often employ broader definitions of child maltreatment than those found in criminal law. In the United States, for example, federal law specifies that child abuse must include "any recent act or failure to act on the part

of a parent or caretaker, which results in death, serious physical or emotional harm, sexual abuse, or exploitation, or an act or failure to act which presents an imminent risk of serious harm" (42 U.S.C. §5106(g)), and most of the individual states employ even broader definitions of maltreatment. For instance, many states specify that making or selling drugs in the presence of one's children constitutes abuse, even if that exposure does not result in serious harm or imminent risk of serious harm to the child. In addition, many states have broad definitions of neglect, hinging on parental failure to exercise a minimal degree of care in providing children with food, clothing, shelter, or medical care or failure to protect children from harms within the home. In these states, judges have found children to be neglected when they are living in dirty homes or exposed to domestic violence, for example, on the theory that children living under such circumstances will not develop properly. Over half of the children found to be maltreated in the United States are in fact neglected pursuant to such definitions (Huntington, 2006).

Given broad definitions of abuse and neglect, disputes arise about whether certain parenting decisions constitute maltreatment or instead are legitimate exercises of parental prerogatives. Corporal punishment is a classic example. Although over 30 countries ban all corporal punishment of children, parents in the United States may generally discipline their children physically so long as the force used is reasonable and moderate, both of which are subject to differing interpretations (Freeman, 2010). Other disputes arise in the context of medical decisions, including with respect to elective surgery, the administration of growth hormones, 'corrective' surgery for intersex children, experimental treatments, and decisions to forego both these and other treatment options. Health decisions at birth are often particularly fraught, with doctors or hospitals appealing to the state when parents refuse to follow treatment recommendations (Wadlington, 1994).

Jurisdictions generally require school officials and health care workers to report suspected child maltreatment to the police or child welfare agencies. In a minority of jurisdictions, this duty extends to anyone who knows about or suspects maltreatment. Child protection agencies then exercise discretion in determining which reports to investigate and how to respond to information discovered during such investigations. In the United States, federal law requires agencies to make reasonable efforts to avoid removing children from parents' homes if the child will be safe. Agencies therefore often work with parents on an informal basis, achieving voluntary changes in parenting practices (Huntington, 2006). At other times, state agencies remove children on an emergency basis, although the United States Supreme Court has held that agencies may not be held liable under federal law for failure to remove children from dangerous homes. Conversely, state agencies may be liable for emergency removals in the United States if the removals are not justified by sufficient evidence of risk of immediate harm to the children removed or if adequate process is not provided to parents. Notably, children's wishes are not part of the calculus in the United States; the state's view of child safety is dispositive at every stage.

When state agencies believe that ongoing judicial intervention is warranted, most jurisdictions oversee such cases in special family courts. These special courts subsequently conduct adjudicatory hearings, overseen by judges or referees without juries, to determine if the state has proven, generally by a preponderance of the evidence, that parents have in fact committed conduct falling within the relevant definition of child maltreatment. In most jurisdictions, legal parents have a statutory right to counsel during these proceedings; stepparents and functional parents who are not legal parents may be considered parents for purposes of such hearings in some jurisdictions. Children have a right to participate in such proceedings in many jurisdictions, at times through legal counsel. In the United States, children are not granted that right but federal law requires that children in abuse and neglect proceedings be represented by a 'guardian ad litem,' who may be a lawyer or a lay advocate, and state law often goes beyond federal law to mandate that a lawyer be appointed instead of or in addition to a lay advocate (Atwood, 2005).

When courts find that the evidence is sufficient to support a finding of child maltreatment, they generally have broad discretion to make a disposition in the best interests of the child. Dispositional options include leaving legal and physical custody with parents, provided they submit to state oversight, the state taking legal custody over children but leaving physical custody with parents, and the state taking both legal and physical custody by removing the child from the home and placing the child with a relative or foster parents or in an institution. With respect to the last option, jurisdictions often permit removal only if the state made reasonable efforts to permit the child to remain in the home, generally by offering services to parents. After removal, jurisdictions also often require states to continue to make reasonable efforts to reunite removed children with their parents.

If children cannot be reunited with their parents, jurisdictions generally terminate parents' rights, so that children may enter stable relationships with new caregivers. In the United States, federal law requires states to file termination petitions, and propose potential adoptive parents, when children have been in foster care for 15 of the most recent 22 months. This requirement is motivated by the view that children generally do not thrive while in 'foster care limbo' and that their best interests are served by a relationship with new legal parents when reunification efforts consistently prove unfruitful (Bartholet, 1999). Pursuant to this goal of establishing new legal parent–child relationships, most of the individual states in the United States require that adoption first be ruled out before proceeding to legal guardianship or other planned permanent living arrangements. Other jurisdictions often embrace a wider range of caregiving alternatives for children, including kinship care, when parental rights must be terminated.

To terminate parental rights absent parental consent, courts generally must find a substantive basis for the termination (severe or chronic abuse or neglect, for example) and that termination is in the child's best interests. Some jurisdictions also permit termination in the absence of ongoing parental fault when it would nevertheless be in the best interests of the child, for example, when neglectful parents have been rehabilitated but the child in the meantime has developed strong bonds with a foster family. As in earlier stages of the proceedings, all children subjected to termination proceedings must

either be represented by guardians ad litem or otherwise participate.

Children's Educational Experiences

The United Nations Convention on the Rights of the Child specifies that all children have a right to an education. In the United States, the Supreme Court has held that access to education is not a fundamental right or liberty protected by the US Constitution, but all state constitutions provide that children have a right to free public education and require state legislatures to establish public school systems. All of these rights to education are also obligations, in that children must attend school regardless of their own desires or the desires of their parents.

Beyond compulsory education laws, laws in many jurisdictions seek to ensure access to quality education for all students. The United Nations Convention prohibits all forms of discrimination against children, including in the context of education. In the United States, the Supreme Court has held that all children, including the children of undocumented immigrants, must be able to access state public school systems that are not explicitly segregated by race. Federal law further prohibits discrimination on the basis of sex and language ability in all schools receiving federal funds and requires all states to provide a 'free appropriate public education' to students with disabilities. Public schools in the United States must also provide 'fundamentally fair procedures' to all students facing expulsion.

Within these parameters, jurisdictions remain largely in control of curricula and policies in state-run schools, even in the face of parental opposition. Parents objecting to school decisions generally lose, based on the theory that local school officials represent the majority views of the relevant population and objecting parents may send their children to privately-run schools (Rosenbury, 2007). The robust conception of parental rights discussed above protects parents' decisions to send their children to schools run by nonstate actors, including religious institutions (Gilles, 1996). Parents generally have no right to state subsidies for private school tuition, however.

This general deference to state educational authority often limits children's autonomy as well as the autonomy of their parents. Students, like their parents, largely have not succeeded in challenging curricula or policies in state-run schools. In the United States, for example, students in public schools have failed in challenges to the removal of books from school libraries and in challenges to school dress codes unless those codes discriminate on the basis of religion, race, or (in some states) gender identity or infringe on political speech that is not disruptive. Public school students in the United States also may not engage in public prayer at school events, or otherwise express religious viewpoints during school-sponsored activities. Students participating in extracurricular activities sponsored by local school districts in the United States must submit to drug testing if the school district so mandates.

Students have succeeded in challenging the practices of state-run schools, however, when those practices infringe on students' individual rights and do not promote other legitimate state goals (Dailey, 2011). The United States Supreme Court, for example, has held that public school students must be given the opportunity to opt out of reciting the Pledge of Allegiance at the beginning of the school day. The Supreme Court has also held that students may express opinions in public schools so long as they do not disrupt or otherwise materially interfere with school activities.

Students in schools run by private actors are not guaranteed these protections, as such schools have wide latitude to develop their own curricula and policies. Students also are not entitled to due process upon expulsion from such schools. Private schools generally must meet minimal educational and health requirements imposed by the state, however. Private schools are also subject to jurisdictions' antidiscrimination laws.

Children's Relationships to the Juvenile Justice and Criminal Law Systems

Most jurisdictions maintain special courts designed to respond to misconduct by children. These juvenile courts, operating apart from criminal courts, reflect the view that children accused of crime should not be punished like adults because children are still developing and thus may be more amenable to rehabilitation than are adults. This focus on development and rehabilitation means that juvenile courts often exercise jurisdiction over a wide range of misconduct by juveniles, including conduct that would not be considered criminal if performed by adults (Scott and Steinberg, 2008).

At the same time, many jurisdictions increasingly view children accused of serious crime as responsible and culpable offenders, just like adults. These jurisdictions therefore try some children accused of crime in criminal courts, or they impose adultlike punishments on children in juvenile courts (Feld, 1993). Protections remain for children even in these situations, however. Most jurisdictions have held that children may not be subject to the death penalty and may not be sentenced to life imprisonment (Feld, 2013a).

Children in juvenile courts receive many of the procedural protections extended to adult criminal defendants, but the protections enjoyed by children are not identical to those enjoyed by adults (Birckhead, 2009). Many of these differences are thought to accrue to children's benefit. Juvenile court hearings are often closed and court records kept confidential. Judges are often permitted to impose indeterminate sentences because it may be difficult to predict in advance how much treatment will be needed to rehabilitate the child offender. The United States Supreme Court has also held that judges in both juvenile and criminal courts must take a child's age into account when determining whether a child was subject to custodial interrogation or validly waived their rights to a lawyer or to remain silent. Other jurisdictions, including some states in the United States, presume that children under a specified age cannot waive their rights or cannot do so without consulting a parent or guardian. Most jurisdictions require that parents be notified before state officials interrogate children (Feld, 2013b).

In other ways children accused of misconduct may receive lesser protections than adults receive. Children in juvenile court proceedings may be detained pretrial on broader preventative grounds than those that apply to adults, and children so detained are often not permitted to post bail. Many jurisdictions permit parents to waive counsel on their children's behalf,

although some jurisdictions require advice from counsel or a judge before parents may do so. In addition, although attorneys representing children in juvenile court proceedings are generally instructed to represent their clients' 'expressed interests,' just as they do for adult clients, parents, prosecutors, and judges often push counsel to instead act in their clients' 'best interests.' Finally, in the United States, children in juvenile court do not have a right to a jury trial, and courts have consistently held that parents may validly consent to searches of their children's living quarters even when similar consent between adults sharing a residence, but maintaining separate bedrooms, would not be valid under the Fourth Amendment (Birckhead, 2009).

Children's Interactions with the Market and Civic Life

All jurisdictions restrict the ability of many children to work for wages. These child labor laws are based on the theory that paid work harms children and society at large by preventing children from obtaining the education needed to develop into productive adults. Children's paid work is therefore regulated very differently than adult labor market participation (Humbert, 2009). Employers who violate these laws are generally subject to civil, and at times criminal, liability. Parents may also be subject to criminal prosecution in many jurisdictions, although most child labor laws contain exceptions permitting children to work under parental supervision in many otherwise prohibited jobs. When children legally engage in paid work, their parents are generally entitled to their wages until they reach the age of majority or are otherwise emancipated, on the theory that such wages offset parents' support obligations.

Many jurisdictions deviate from this norm of differential regulation of child and adult labor in one employment context, prostitution. Although the United Nations Convention on the Rights of the Child requires states to protect children from sexual exploitation, and the United States similarly has robust laws criminalizing child sexual abuse, jurisdictions that criminalize prostitution tend to treat children engaging in sex work the same as adults. This equal treatment has been criticized on multiple grounds (Birckhead, 2011). Some argue that the practice is illogical, as some children are prosecuted for prostitution even when they are under the minimum age for consenting to sexual intercourse. Others argue that children, unlike adults, are incapable of consenting to prostitution. Defenders of the practice emphasize, however, that the prosecution of child prostitutes keeps vulnerable children off the streets and induces children to cooperate with the prosecution of their pimps.

Outside of the employment context, children may enter into contracts and enforce them against other parties, but many jurisdictions also permit children to disavow most contracts at any time during their minority, or within a reasonable time after becoming adults, by invoking the infancy defense. To disavow the contract on this basis, children must return the purchased goods that remain in their possession, if any; if the contract was for necessaries, children must also return whatever value they received from the goods. Some jurisdictions go farther, requiring children to make restitution for the benefits received from any disavowed contract or to pay quasi-contractual damages in some contexts beyond the context of necessaries. Children are thought to be protected by this general approach, but the availability of the infancy defense also makes many parties reluctant to enter into contracts with children (Preston and Crowther, 2012).

At the same time, children increasingly engage in commerce, particularly electronic commerce, and companies often aggressively advertise to children as consumers. Some jurisdictions impose additional regulation on advertising targeted to children, given that children may be more subject to manipulation than adults. Some jurisdictions also impose additional regulation designed to protect the privacy of child consumers. In the United States, for example, federal law requires web sites and other online services that knowingly collect personal information to obtain parental consent before collecting such information from children under 13 years of age.

In other market contexts, children's decisions are accorded the same respect extended to adults. In many jurisdictions, children on their own may seek contraceptive, prenatal, and abortion services, as discussed in more detail in the next section, and may seek treatment for sexually transmitted diseases or drug and alcohol abuse (Hill, 2012). In the United States, the Supreme Court also recently held that states may not limit the sale or rental of violent video games to children. In reaching that holding, the Court emphasized that although "a State possesses legitimate power to protect children from harm," that power "does not include a free-floating power to restrict the ideas to which children may be exposed" (Brown v. Entertainment Merchants Ass'n, 131 S. Ct. 2729 (2011)). In a similar vein, courts have held that schools may not limit student speech on social networking sites, so long as students did not intend for the speech to reach the school and there is no reasonable forecast that the speech would cause substantial disruption at school (Waldman, 2011).

In addition to engaging with the market, children may inherit property or receive property as gifts, and parents do not automatically enjoy legal power over such property in many jurisdictions. Children holding sole title to such property often encounter problems effecting transfers or sale, however, given that the contracts of children are voidable, as discussed above. In addition, children generally may not execute valid wills or file lawsuits until they reach the age of majority or are otherwise emancipated (Cunningham, 2006). Given such issues, courts may empower parents or other guardians or custodians to manage the property subject to fiduciary duties or court supervision. In order to achieve more flexibility, some donors or decedents convey property to children through trusts, wherein the trustee holds title to the property and manages it for the benefit of the child beneficiary.

Children's participation in civic life is more limited than in the market. Although all jurisdictions recognize children as citizens, if they or their parents meet certain requirements, that citizenship does not enable children to vote. More than a dozen nations have lowered the voting age to 16 years for purposes of at least some elections, but no jurisdiction has permitted children less than 16 years of age to vote (Hamilton, 2012). Some believe that children's political interests are represented by their parents, but parents neither receive more votes than

other adults, nor are parents permitted to vote by proxy on behalf of their children.

Children's Peer Relationships

Law focuses most of its attention on children's relationships with adults, whether they are parents, other adults serving as parents at the direction of the state, teachers, or juvenile justice personnel. Law generally does not recognize or otherwise respond to children's relationships with peers, except in two, relatively narrow circumstances: sibling relationships and harmful peer relationships.

Jurisdictions confer legal status on sibling relationships, and some states in some circumstances recognize stepsibling relationships. The effect of that status is often confined to the context of inheritance law, however. Laws in many jurisdictions direct judges to take sibling relationships into account, by keeping siblings together or arranging for meaningful visitation, when making custody or maltreatment decisions, but attempts to keep siblings together often fail, particularly in maltreatment proceedings. In the face of such failure, most jurisdictions do not guarantee that siblings may live with one another or even visit one another in different households (Hasday, 2012).

Accordingly, if the parent–child relationship falls apart, the sibling relationship is not always protected. Moreover, the value of sibling relationships is often assumed to flow primarily from the common parent–child relationship. For example, some states in the United States prohibit judges from terminating parental rights when doing so would substantially interfere with sibling relationships. Yet to preserve sibling ties, children in this context are moved into guardianship instead of termination of parental rights and adoption. Although some children may benefit from guardianship, other children may benefit more from adoption. By protecting sibling ties only by preventing the termination of parental rights, parents may benefit more than children.

Organ donation between siblings also raises complex legal and ethical issues. Siblings often provide the best match as donors, and parents often want one sibling to donate to another. In disputed cases, courts generally look at the best interests of the donor child, sometimes applying the substituted judgment rule under which the court determines whether the child would agree to be a donor if the child were old enough to make the decision (Hill, 2012). In reaching this conclusion, courts tend to consider the psychological relationship between the siblings, whether the donation will help keep the relationship intact, and the physical risk to the child donor.

Outside of the context of sibling ties, jurisdictions generally respond to children's peer relationships only when those relationships are perceived to be threatening to the children themselves, to other children, or to larger communities. In such situations, law often authorizes state intervention designed to end the peer relationship and alleviate the harm. For example, the US Supreme Court has interpreted federal law to impose tort liability on schools that fail to protect students from harassment by other students on school grounds. Many jurisdictions have also adopted antibullying statutes and policies and passed various forms of antigang legislation (Silbaugh, 2013).

Other forms of state intervention are less directly coercive, but they still attempt to alleviate the harm presumed to flow from children's peer relationships. By passing curfew ordinances that limit the hours in which children may congregate outside of the home, for example, jurisdictions implicitly recognize that children seek to interact with one another but seek to limit that interaction in order to prevent potential harm. In the United States, children are generally permitted in public after curfew hours only when accompanied by a parent, engaging in an organized activity approved by a parent, or running an errand for a parent, thereby reinforcing the primacy of the parent–child relationship while simultaneously positing children's unsupervised peer relationships as threatening and unsafe (Federle, 1995).

Sexual relationships between children are often viewed as particularly threatening. Some jurisdictions criminalize teen sexual behavior in the hope that potential sanctions will deter some children (generally boys) from pursuing sex and encourage other children (generally girls) to resist. Children often are not prosecuted under such statutes, however, and the few prosecutions that occur often appear motivated by concerns about particular sexual practices, including those between same-sex partners and partners of different races and those that result in pregnancy (Goodwin, 2013). In the United States, some children have been charged with violations of child pornography laws when they sext one another, even when they are sending their own images to peers (Sweeny, 2013–14).

Some jurisdictions, in particular the United States, also do not affirmatively provide children with the means to manage the reproductive and health consequences of sexual relationships. Public schools in the United States often offer limited sex education, and none of the states mandate that schools provide children with condoms or other contraception (McClain, 2006). Some public schools in the United States have chosen to distribute condoms on their own, however, and courts have rejected parental challenges to such distribution so long as schools permit parents to veto their children's access.

In other ways, jurisdictions address the consequences of children's sexual relationships as part of public health initiatives (Hill, 2012). Most jurisdictions, including the United States, allow children to consent to treatment for sexually transmitted diseases or drug and alcohol abuse without requiring them to notify their parents. Many of these jurisdictions also mandate that girls be vaccinated against the HPV virus, which is transmitted sexually. Many jurisdictions similarly allow children of certain ages, generally 12 and older, to seek contraceptive services without parental involvement. Children's access to abortion is more tightly restricted, particularly in the United States, where only two states explicitly allow all pregnant children to consent to abortion on their own, without parental involvement.

Assessing Law's Role in Children's Lives

This general approach to allocating legal authority over children serves multiple goals. Law treats children as a distinct legal category because children are legal subjects with vulnerabilities, developmental needs, capacities, interests, and experiences often different from those of adults. Law defers to parental

prerogatives in most contexts in order to encourage parents to invest in and provide for their children, both in terms of responding to children's incapacities and dependencies and in developing the close relationships necessary for nuanced decisions about each child's unique circumstances (Buss, 2004; Dailey, 2006). Robust norms of family privacy also foster diversity and pluralism (Cooper Davis, 1994; Galston, 1998). At the same time, the state retains an interest in protecting and educating children in order to ensure they are properly prepared for the obligations of citizenship.

Debate remains about whether law could better achieve each of these goals and whether law's current focus frustrates other goals. In particular, law's focus on the appropriate allocation of childrearing authority between parents and the state may create a perception of children as objects to be possessed (Woodhouse, 1992) which, in turn, may detrimentally affect children's perceptions of their own autonomy. Law's emphasis on children's dependency, and adults' responsibility for children's welfare, may similarly overlook the ways that children gradually attain the ability to act autonomously. Accordingly, some lawmakers and scholars increasingly have recognized children's developing capacities, positing a continuum between infancy and adulthood, with children acquiring greater decision-making abilities as they grow older (Dailey, 2011; Zimring, 1982). As discussed above, this approach currently comes into play most often with respect to state regulation of adolescent decision making outside the home, particularly in the market and when children are accused of serious crimes, but the approach could also be invoked to support children's agency even within the family.

Law has yet to develop a systemic approach for deciding whether children's dependencies or capacities should govern particular contexts or a mechanism for combining the strengths of each approach. Doctrinal inconsistencies therefore abound (Appleton, 2014). For example, many children accused of committing crimes are adjudicated in juvenile courts on the theory that they lack the capacity and maturity to be held fully responsible for their crimes. This treatment resembles the legal treatment of children in other areas where doubts about children's decision-making abilities exist, such as voting, driving, and sexual relationships. At the same time, doctrines in other areas, such as free speech and reproductive rights, reflect greater deference to children's decisions, and many children are tried in criminal courts based on the severity of their crimes alone without regard to their decision-making abilities. Approaches privileging children's dependency over their capacities, or their capacities over their dependency, thus have failed to produce a coherent body of law governing children's lives.

In addition, these approaches are limited in their aspirations, emphasizing children's dependencies and capacities while minimizing other important interests. Dependency and autonomy do not capture the full range and complexity of children's experiences. Children also live active lives in the here and now, experiencing a full range of emotions and interactions as children, separate from or in addition to their interests in becoming adults, even as they are dependent on adults for many aspects of their lives. By focusing almost entirely on children's relationships with adults or the contexts in which children might be treated like adults themselves, lawmakers and scholars often overlook the ways that children are more than passive recipients of adult childrearing until they become adults themselves. Law thus minimizes children's intrinsic experiences.

This article offers a broad survey of the diverse ways that law governs children's lives as a way of understanding existing frameworks of children and law and envisioning new ones. Law does more than regulate children within the family or in state institutions. Instead, law mediates children's interactions with multiple actors in multiple spheres across public and private divides. Law's traditional approach of allocating decision-making authority between parents and the state serves many purposes, but law does and can do more to respond to and facilitate the full range of children's needs, desires, and experiences.

Abstract

This article reviews the historical development of children's rights worldwide. It then describes the different categories of claims made under the rubric of children's rights and discusses value issues that need to be resolved as governments, courts, and citizens seek to define children's status in each society. It concludes by examining the challenges countries face implementing any such rights.

The last 100 years have witnessed enormous progress in the recognition of individual human rights throughout the world. In addition, various identity groups, including women, racial, ethnic, linguistic, cultural and religious minorities, the disabled, and gay males and lesbians all have claimed, and received to varying degrees, rights to equal treatment under law, nondiscrimination in employment in both the public and private sectors, and fuller integration into the economic and political life of their countries.

It is perhaps not surprising, therefore, that a worldwide movement to recognize children as a distinct subgroup with claims of rights also occurred. In 1924, the League of Nations adopted the first Declaration of the Rights of Children. In 1989, the United Nations General Assembly adopted the UN Convention on the Rights of the Child (UNCRC) (UN Convention, 1989), which has been called the 'most comprehensive and detailed of all … international human rights instruments' (Alston, 1994: p.1). The Convention has been ratified by 192 of the 194 UN members; the United States and Somalia have not ratified. In the United States, conservative political groups, concerned that the CRC (Convention on the Rights of the Child) undermines parental authority and gives government too much power over families, have contributed to blocking ratification. In Somalia, there is no internationally recognized government, which precludes ratification.

Despite the seemingly widespread acceptance of the concept of children's rights, the idea that children, individually or as a class, should have *rights* (claims enforceable against others) is actually revolutionary and problematic both in philosophical and practical terms. Determining what rights to provide children requires that societies confront fundamental value issues quite different from those entailed in recognizing other groups' claims.

First, children generally are not autonomous; they are dependent; moreover, the period of dependency has lengthened with modernity. Ideally, they are part of families; their life chances are greatly affected by the care they receive from their families. Parents need authority to fulfill these responsibilities. Some highly respected child development specialists argue that giving children rights may be incompatible with sound child development (Goldstein et al., 1973). In addition, giving children rights may conflict with parental rights and privacy. However, parents do not always act in their children's best interests and the community as a whole has an interest in the development of future generations. Children may have their own views and desires. Therefore, it must be decided how responsibility for the well-being and upbringing of children should be allocated between parents, families, the child, and the community as a whole.

Second, intellectual and emotional capacities develop gradually, for both biological and social reasons. These limits in capacity may conflict with claims that children should have the same liberties and privileges as adults (Purdy, 1992). A theory of children's rights must address the question, what entitles persons to be full participants in a country's civil and political life?

The term children's rights encompasses five different claims. Most important is the right to be recognized as persons and therefore entitled to basic human rights, including the right not to be 'owned' by another. The worldwide acceptance of this premise reflects a fundamental shift in the conception of children. However, this right may conflict with parents' right to form their children's values and life plans. Second is the right to have government guarantee their basic well-being, by assuring adequate food, shelter, and health care. While children clearly need these goods, there is disagreement whether such support should be considered a right or a moral obligation of citizens to each other. Third is the right to protection from inadequate care from caretakers. While this right is accepted everywhere, the definition of inadequate and the degree of justifiable state intrusion to protect children remains highly debated. The fourth category focuses on liberty and participation rights, such as the right to freedom of expression and the right to vote. Supporters of liberty rights must develop a theory of why children should be granted some rights and not others. The final category involves children's right to act independently of parental control. There is no easy resolution to the tension between parental rights and children's rights. Children cannot have total freedom from parental control, both because this would often be harmful and the state cannot regulate most intimate family relations. There may be areas, however, where the consequences of not giving children rights outweigh the harms of limiting parental oversight of their children, for example, the right to receive certain medical care or access to contraceptives without parental permission.

The Historical Context

For much of history children were viewed largely as nonpersons, the property and responsibility of their parents, who had a right

to control their upbringing, even their very existence (Eekelaar, 1986). Children (usually defined as persons under 21 or 18 years of age) also could not participate in the political or civic life of their countries.

In the mid-1800s, some countries began assuming state responsibility for promoting and protecting children's well-being. Initially, this entailed providing free public education and passage of laws protecting children from severe physical abuse by their parents. Over the next 100 years, Western industrialized countries adopted more laws affecting the status of children, including laws limiting child labor in settings outside the family, passage of compulsory school attendance laws, and greater state efforts to protect children from parental maltreatment. The idea that childhood was a period for gradual maturation and lesser responsibility also was reflected in the creation of the juvenile court, which was directed to treat, not punish, children who violated the law (Hawes, 1991).

While these policies were advocated in the name of children's rights, and certainly contributed to their well-being, these were not the types of civil rights that other groups were demanding and receiving. The focus was on the protection of children, not their autonomy or fuller integration into the economic and political life of their countries. Moreover, except where their behavior was considered inimical to the social order, parents continued to have virtually total authority over their children's upbringing. In the United States, where the movement toward child protection was most evident, the US Supreme Court ruled early on that parents had a constitutional right to control their children's upbringing (Meyer v. Nebraska, 1923).

In fact, many 'children's rights' laws often were supported primarily as a means of protecting adult interests. For example, child labor laws and compulsory schooling were championed by newly emerging labor unions, which viewed the availability of child labor as a barrier to higher wages for adults (Woodhouse, 1992). Proponents of the juvenile court promoted it as a needed intervention to protect society from children who were not being adequately supervised by their parents, often poor, immigrant parents (Schlossman, 1977).

Since the 1960s, most countries have continued expanding the protection of children's well-being. The establishment of a right to education for virtually all children throughout the world increased state efforts to guarantee children a minimal level of material well-being, and greatly expanding state intervention into family privacy through child abuse laws that have all benefited children. Moreover, during this period, in many countries children were recognized as rights holders with respect to freedom of speech and other civil liberties, were given a greater voice in decisions affecting their lives, such as custody decisions when parents divorce, and in some situations have been given a degree of legal autonomy over behaviors once controlled by their parents, for example, access to contraception.

Yet the scope of applicable rights remains highly contested. At the extreme, some commentators have argued for 'children's liberation,' with the complete elimination of distinctions between children and adults with respect to all political, social, and familial rights (children, as reflecting of their status, usually have not been the demanders of these rights, in contrast to other groups). For example, they argued that children should have the right to vote, to decide whether to go to school, and to a share of the family income to spend as they choose (Farson, 1974).

Few proponents of children's rights go this far. Most advocates propose limiting, but not eliminating, parental autonomy in controlling their children's lives and giving children increasing autonomy as they mature, in recognition that capacities develop over time. Yet even the more limited types of claims of rights raise profoundly difficult issues.

What Is Meant by Children's Rights?

As noted, the term children's rights is used to encompass a variety of different claims (Campbell, 1992). Rights for adults generally involve claims to be autonomous. While this also is true of some children's rights, often the term is used to support the argument that adults should act in a manner that protects children's best interests. Distinguishing these categories reveals the tensions in the general concept and helps identify the issues related to the implementation of various types of claims. Often this entire debate revolves around who is in the best position to determine the child's 'best interests' – the state, the family, or the child?

Basic Human Rights

The first claim is that children are entitled to basic human rights, including the right to life itself, the right not to be 'owned' by another, the right to freedom from torture or other cruel punishment, and the right to be free from discrimination based on race, color, gender, religion, or national, ethnic, or social origin. Such rights are widely accepted for adults, despite continuing problems with implementation, especially with respect to nondiscrimination based on gender, race, and ethnicity. Since these rights are not tied to competence or capacity, there is no reason for denying them to children on this basis. The critical step is accepting that children are *persons*, not chattels or incomplete human beings. By adopting the 1989 CRC virtually all countries accepted this fundamental shift in the conception of children, although the ongoing differential treatment of girls, including the practice of infanticide and limiting schooling, remains a significant problem in many countries.

Moreover, application of these rights to children is not entirely unproblematic, at least with respect to the relationship between parents and children. Few countries still consider children to be the property of their parents. However, many people agree with Fried that "the right to form one's child's values, one's child's life plan … are extensions of the basic right not to be interfered with in doing these things for oneself" (1978). Yet, such a right constitutes a form of 'ownership' and may conflict with the child's right to an 'open future' and with society's interest in how future adults are socialized (Feinberg, 1980). The increase in home schooling in the United States beginning in the 1990s and the denial of education to girls in many countries are reflections of the tension between a liberal view that children should be given the opportunity to become autonomous adults able to choose their own ends and the view, often derived from religious values, that children should

be raised in a manner that maximizes the likelihood that they will accept specific religious or cultural norms. (I am not sure where the sentences I have deleted came from: they do not seem to fit here.)

There is no easy resolution to this conflict about the location of rights and responsibilities. Unless the state were to intervene in family life in ways that would be deemed unacceptable in most countries, parents will continue to make critical decisions for children, regardless of the child's wishes. As noted, respected child development experts assert that parents need autonomy to successfully raise their children. Moreover, deference to parental or family authority may be demanded by a society's political, cultural, or religious traditions. In some countries, including the United States, supporting parental autonomy is seen as critical to supporting political and cultural diversity. In others, the proper role of parents may be seen as teaching children to accept national cultural values and traditions, not as helping children develop into 'autonomous' adults (see generally Alston, 1994). Many countries have reserved the right to apply the CRC in light of their own cultural or religious laws, although there is evidence that the CRC is influencing these values (*International Journal of Children's Rights*, 1995). Whether children's rights are universal or culturally specific likely will remain one of the major debates in implementing the CRC. For recent studies, see the chapters in the edited volume by Invernizzi and Williams (2011).

In fact, given that children's values and perspectives are malleable and constructed, someone will shape their values and personhood. Parents, families, neighborhoods, peers, government institutions such as schools, and general cultural norms all play a part. Thus, the issue is what are the appropriate roles of the family and the state in making critical decisions, such as those regarding schooling, religion, where the child shall live, not whether children should have the right to control their own upbringing (Coons et al., 1991). This question goes to the heart of how a society defines the relationship between the state and the individual, adults, and children alike.

Children also are denied some basic civil rights available to adults because societies have an interest in how they are socialized. At a minimum, children are compelled to go to school, thus restricting their liberty rights. Finally, there is still substantial debate over the status of the fetus with respect to abortion and maternal behavior during pregnancy. Because no consensus could be reached on this issue, the CRC leaves the question to each country.

Despite these problems, the recognition that children are persons, with rights, along with the acceptance of the basic premise of the CRC that in all decisions affecting children their 'best interests' shall be a primary consideration, constitutes a great advance that clearly benefits the vast majority of children.

Welfare Rights

A second category of claimed rights is that government should guarantee children a basic level of well-being; these are often called welfare rights. The CRC provides that children should have a right to "a standard of living adequate for the child's physical, mental, spiritual, moral, and social development" (Article 27), "the enjoyment of the highest attainable standard of health…" (Article 24), and to education (Article 28). The CRC goes beyond these basic goods, and seeks to afford children a broader set of welfare rights, including the right "to rest and leisure, to engage in play and recreational activities appropriate to the age of the child and to participate freely in cultural life and the arts" (Article 31).

Since the 1950s, governments have assumed increasing responsibility for guaranteeing that children have adequate food, nutrition, shelter, and health care. In many countries, children benefit from general social welfare policies, which provide all citizens with universal health insurance and various forms of income support. Most industrialized countries also have partially socialized the cost of caring for children through children's allowances, paid parental leave after the birth of a child, and public provision of day care. Many less economically developed countries are moving in the same direction, despite limited financial resources.

The laggard in this regard, given its capacity, is the United States. Despite its wealth, approximately 20% of children in the United States live in poverty. Resistance to greater income support for children in the United States reflects, in part, the belief of many political figures that childhood poverty is caused by 'irresponsible' adult behavior, such as having children out of wedlock, and that it is impossible to provide goods to children without also giving them to adults, thereby 'rewarding' the adults' actions. In addition, many politicians support the premise of libertarian theorists like Robert Nozick that there is no moral justification for the redistribution of wealth (1974).

Even in countries that accept a welfare state, the level of support that a child should receive remains largely a political issue, not a legal right enforceable by courts. No matter how wealthy a country, trade-offs between levels of socially provided health care, housing, education, and other welfare goods are now seen as inevitable. Courts, appropriately, are reluctant to get too deeply into these decisions. Since the scope of the claimed right is so vague, courts lack the legitimacy and authority to order elected governments to provide people with specific levels of well-being. In addition, some theorists contend that, in the political process, framing political debates in terms of moral obligations that the citizens of a country pledge to provide to each other may prove more productive than trying to establish rights (O'Neill, 1988; cf Freeman, 1992).

Another critical question is whether welfare rights should encompass the right to 'equal opportunity.' Opportunity focuses on each child's options in adulthood. Social scientists have struggled to identify the goods that must be provided to children during childhood in order to equalize their opportunities as adults. Much of the focus is on education. But opportunity is also highly influenced by the quality of parenting a child receives and the social, economic, and cultural environment in which the child is raised. A right to equal opportunity is far more difficult to guarantee than a right to basic necessities and may require restricting parental rights (Fishkin, 1983).

Protection Rights

A third category of claimed rights for children is protection from inadequate care from their caretakers, especially their

parents. Since giving children more protection changes their relationship with their parents and the state's relationship with parents and families, this right raises fundamental issues quite different from welfare rights.

The degree of justifiable state intrusion against a parent's will remains highly debated. Should the state treat parents as 'stewards' or 'trustees' of their children, and seek to ensure that parents provide children a high level of care, or should the state be the protector 'of last resort,' intervening only if parental care is clearly harmful?

Most countries have decided that coercive intervention should be limited to situations where the actual or threatened harm to the child's physical or emotional well-being is substantial. This approach reflects the judgment that unwanted intervention is a drastic step from the child's, as well as the parent's, perspective. It also is based on evidence that the care provided to children removed from their families sometimes is as bad as or worse than the parental care (Wald, 1982). Even when some form of state intervention is needed to protect children, many countries are following the practice, first established in New Zealand, of maximizing the involvement of parents and extended family in deciding how best to protect the child in the future. In the United States, there is a preference for placement with kin when a child must be removed from the parent's home.

A few countries have adopted laws that seek to provide more extensive protections for children. Five countries have banned any corporal punishment of children; while these laws do not carry any significant sanctions for violation, they reflect a different conception of the rights of children and the role of the state. In recent years, evidence that early child rearing can substantially affect a child's brain development and capacity for school performance and social regulation has led to increased calls for more extensive monitoring of how each child is being reared (Shonkoff et al., 2011).

In the future, governments will continue to struggle with the appropriate grounds for protective intervention. The critical task, however, will be to develop and connect children to social programs that enhance all children's well-being and future opportunities without resorting to coercive interventions. By the time protection rights must be invoked, the child has suffered substantial harm and the capacity of the state to rectify the situation is often limited (Lonne et al., 2009).

Liberty and Participation Rights

The fourth category of rights does focus on autonomy. In virtually all countries, persons under 18 lack the right to vote, they are restricted in making decisions about whether to work (but compare the widespread use of child labor in poorer countries), and in their freedoms of expression and other civil rights. In addition, in many countries children accused of criminal behavior generally are denied some due process rights available to adults in that country, for example, the right to a jury trial; these limitations have been justified as necessary to promote the rehabilitative ideals of the juvenile justice system.

In 1967, the US Supreme Court determined that children are entitled to at least some of the rights guaranteed by the free speech provision of the US Constitution (Tinker v. Des Moines Independent Community School District, 1969). Since then the liberty rights of minors have been gradually increased in the United States and many other countries. The CRC provides that: "(the) child shall have the right to freedom of expression; this right shall include the freedom to seek, receive and impart information and ideas of all kinds, regardless of frontiers, either orally, in writing or in print, in the form of art, or through any other media of the child's choice" (Article 13); "(s)tates parties shall respect the right of the child to freedom of thought, conscience, and religion" (Article 14); "(s)tates parties recognize the rights of the child to freedom of association and to freedom of peaceful assembly" (Article 15). Notably, the CRC does not provide adult status in other areas, such as the right to vote, marry, work, or to be free from constraints imposed only on children, such as the obligation to attend school, or to be at home by a certain hour (curfew laws).

Courts, legislatures, and the drafters of the CRC have not arrived at any consistent theory justifying granting children some of these rights and not others. Nor have they resolved the tension between claims for special protection and for full participation. If adolescents are seen as having the maturity and capacity to make decisions about their health care, to choose what they read or see, or to vote, does it not then follow that they should be held fully responsible for their antisocial behavior? While few child advocates would go so far, this claim was invoked in the United States to justify prosecuting juveniles who commit serious offense in adults courts.

The critical issues relate both to capacities and to questions about developmental needs. For some rights, such as voting or marrying, it is generally accepted that some minimum level of competence is necessary to the proper exercise of the right. Children often are denied other rights, such as unlimited access to books or movies, on the assumption that early exposure to certain materials or ideas may be harmful to them.

An overriding question is whether it makes sense to assume that the same age line should govern access to all political and civil rights. Zimring has proposed treating children as possessing a 'learner's permit,' whereby they are given increasing autonomy and responsibility over time (1982). Different rights might be available at different ages, based on best guesses about average capacity. Age lines are inherently arbitrary; not all people attain capacities at the same age. But individualized decisions about whether someone is old enough to vote, marry, or leave school are likely, in practice, to be even more arbitrary, as is having a single age trigger all rights.

Autonomy within the Family

The issues regarding autonomy rights are even more difficult with respect to the right of children to act independently of their parents' wishes. The extreme view, that children of any age should be free to make their own decisions, has not received acceptance. In many countries giving children any autonomy within the family would be incomprehensible. In other countries, there are debates about whether children should have a right to make certain major decisions, such as whether to have an abortion, to have access to contraceptives, or to receive treatment for substance abuse, without their parents' permission or knowledge. Advocates of giving children these rights contend that many children will be reluctant to seek out needed services if their parents are informed. Children have

also been given some rights to determine important aspects of their life, such as which parent to live with in the case of divorce-or at least to have their voice heard in legal proceedings affecting their interests. The case for giving children rights is strongest with respect to decisions where parents may not be counted upon to generally act in their children's best interests.

There is no easy resolution to the tension between parental rights and children's rights. It is unrealistic to assume that children can have total liberty rights, enforceable against their parent's opposition. Asking courts to enforce most such rights would be a waste of court resources and the orders would be unenforceable as a practical matter. But giving children some rights is feasible, for example, access to drug treatment or abortion without parental permission. The question is whether the benefits of giving children autonomy with respect to the decision outweigh the harms of limiting parental oversight of their children. These rights will have to reflect the legal and social structure of each country and should not be thought of as universal children's rights.

The Future

The situation of children throughout much of the world improved substantially during the twentieth century. Concepts of rights likely contributed to these advances. The recognition that children are independent human beings with claims to special attention and resources is a major advance with respect to universal recognition of human rights (Freeman, 1992).

However, further development of children's rights will require resolving the value issues often masked by rights talk. Despite the unprecedented rapidity of the ratification of the CRC, the fact that the contours of many of the proposed rights are not very clearly defined will make enforcement and monitoring by the international bodies problematic. In fact, the very vagueness of the obligations may account for the rapid ratification and almost total support of the CRC, despite the fact that many of the proposed rights seemingly conflict with deeply held cultural and religious values in many countries. Countries expect to interpret the provisions in light of their customs and values. But progress is definitely being made; for example, many countries have children's rights ombudspeople or children's commissioners that seek to educate the public and enforce the Convention.

With respect to welfare rights, those concerned with helping children must recognize that realization of most of the proposed rights requires policies that help families, not just children (Luttrell-Rowland, 2012). Children's well-being generally is inseparable from that of the parents. Greater provision of welfare rights should lessen the occasions that protection rights will need to be invoked. However, in establishing welfare rights, countries need to ensure that when adults seek to act on behalf of children, their own needs do not take precedence.

With respect to all general social policies, countries must think through the implications of the fact that children, who may constitute a third to half of the population, cannot vote. The poorest children are further disenfranchised by the general powerlessness of their parents. Some countries are making significant efforts to include the voices of children in discussions of issues related to them and to more general public policy issues. For example, in the United States, youths are often members of commissions created to assess public policies and a number of cities have youth commissions. Children were involved in Nepal when it considered adoption of the CRC. The recognition of children's right to speak for themselves could significantly alter the place of children in the state (Melton and Limber, 1992).

Many countries continue to deal with problems of street children, child prostitution, child labor, and infanticide. The advancement of children's rights in these countries will be intimately linked to women's rights, since it is unlikely that children will have economic security and greater liberty if their mothers lack these rights. It will also require wealthier countries to demonstrate concern for children beyond national borders.

Children's rights advocates sought to make the 1900s, the century of the child. They were successful in many respects. Future advances will require finding adequate balances for the tensions that have been identified, as well as eliminating the negative impacts on children of discrimination based on race, class, and gender. For most children, these latter factors may be greater barriers to their rights and well-being than age.

Children's Geographies

Claire Freeman, Geography Department, University of Otago, Dunedin, Aotearoa, New Zealand

Abstract

Children's geographies, or more correctly the geographies of children and young people, explore the relationship between children, young people, and space. Space matters as it impacts directly on the ways children interact with society and on their physical and mental well-being. It is also an important determinant of their life chances. Children's geographies is increasingly recognized as a significant focus of geographical research, especially in relation to the lives of children in the majority world. Children's lives are being directly affected by the changing global environment. Children's geographies has much to offer in understanding and responding to these changes.

What Is Children's Geographies?

Geography involves the study of space and place, its formation, character, and, significantly, the interaction between place, society, and individuals within that society. For children, space is critical; it determines their well-being and life chances, it molds their identity, influences behavior, and provides the stage on which they find their way in society. Children are shaped by and in turn shape the physical worlds in which they live, and in this regard space matters enormously. Geography with its disciplinary focus on space and society is ideally placed to contribute to better understanding children's lives. Children's geographies, therefore, is the study of the relationship between children and space. However, the reality is far more complex than this simple relational definition suggests.

Childhood itself is a highly contested notion. Definitions and concepts of childhood differ. Childhood can be defined chronologically but clarity over what constitutes the age of childhood is contested. The United Nations Convention on the Rights of the Child (UNCROC) defines a child as being up to age 18; however, few young people appreciate the appellation of child. Many organizations concerned with children's well-being use the phrase children and young people. Yet, the term young person is itself problematic as in some contexts it refers to someone up to age 25. Childhood can also be defined with reference to access to rights. Again these are age-variable by country and context. For example, the age of criminal responsibility in India is age 7.

Children's geographies generally follows the UNCROC definition of a child being aged under 18 but uses the term young people for children of secondary school age or beyond. The term children's geographies is in some ways a misnomer, as its focus is not just on children but on young people, so really should be called geographies of children and young people. Neither is 'children's geographies' purely the prerogative of geographers, rather it is a coalescence of research around children's geographies undertaken by researchers from a range of disciplines. It is characteristically and increasingly multidisciplinary in both participation and content, and has application to a range of professions including education, psychology, sociology, anthropology, urban design, architecture, planning, transportation, and health studies.

Development of Children's Geographies as a Discipline

Children were conspicuously absent from geography for most of the discipline's early development. The 1970s and early 1980s saw a number of early studies on children from a geographic perspective. Bunge is usually credited with providing the first focused geographical study of children for his work on spatial oppression and children in Detroit and Toronto (Bunge and Bordessa, 1975). Other significant early works include those by Colin Ward (1978), Roger Hart (1979), and Roger Moore (1985). The works of Hart and Moore broke new ground in studying children's use of space as they took their lead from the children in their research. Child-led research is now seen as good practice, but at that time it was groundbreaking in its novelty. While these were significant works, children's geographies as a discipline usually takes its starting point from the article by James (1990) which asked "Is there a 'place' for children in geography?" The answer to James' question is a clear 'yes,' as children's geographies has grown markedly since then and is a clearly recognized subdiscipline in geography that has its own journal, holds international conferences, and is supported by a wealth of scholarly work. As well as research being published in the journal *Children's Geographies*, children-focused studies are now being published in a wide range of geographical journals. However, despite this growth, within geography, children's geographies, like children themselves, is seen as a worthy endeavor but has a limited voice and is generally consigned to the margins of mainstream geographic thought. Children's geographies has received considerably less attention from geographers than the geographies of adults. This is unfortunate, particularly in terms of the potential for children's geographies to offer insights into wider geographical research and current areas of concern, notably research on creating more resilient environments (Skelton and Gough, 2013).

A Schema for Children's Geographies

The field of children's geographies, like the subdiscipline itself, has broadened and matured. In 1999, Matthews and Limb proposed an agenda for the geography of children, putting

forward seven propositions focusing on children's geographic relationships. Their agenda identified that children differ from adults in their 'ways of seeing,' place use, free range, environmental fears and sense of danger, place feelings, relationship to environmental decision making, and democratic responsibility. This agenda has stood children's geographies in good stead, but in recent years increasing attention is being paid to wider concerns, notably developing and challenging the ways that children are conceptualized and positioned in society.

Children's geographies has been instrumental in challenging children's absence from and marginalization in society in respect to their knowledge and voice, and in repositioning children as a focus of study in their own right, rather than as adjuncts to adult-based studies. This repositioning is important as it has given recognition to children as social actors who are knowledgeable, competent, and capable of coherently articulating their views. Thus, children are seen as dynamic agents capable of not just being acted on by the environment and society, but also through their own actions, themselves shaping the environment and society. They are, therefore, not just adults in waiting but capable social actors in their own right. This maturing of how children are represented and the emerging agenda is most apparent in the contemporary development of what has been termed 'new social studies of childhood'; its foundational principles are:

1. to explore the social construction of childhood and youth;
2. to critique the assumption that childhood is universally experienced and understood;
3. to foreground children and young people's own issues, experiences, practices, and perspectives; and
4. to recognize and explore children's and young people's agency in their lives and in broader social structures (Kraftl et al., 2012).

While these foundational principles are well intentioned and have the potential to promote both children's well-being and broader social agendas, the reality is that challenges persist in promoting change in policy and practice. Despite the upsurge of interest in the lives and well-being of children, recognition of children's social and environmental rights remains limited (Freeman, 2007). Enabling children and young people to take up a full role in society requires adults to take a more child-focused and supportive role and to devolve to children and young people some of the power they currently hold. Whether societies and institutions are ready for this remains uncertain as the values that at one time suggested that 'children should be seen but not heard' are still evident (Freeman and Tranter, 2011).

A Global Discipline

Understanding of and engaging with children's geographies is increasingly important for a number of reasons. Children are part of an increasingly spatially extensive and complex world. They reflect highly varied social and geographical relationships that occur at a diversity of scales from local home neighborhood to the global. Children are increasingly mobile as they move within and between homes, schools, and various service spaces. This mobility can comprise microscale movements as in daily or weekly movements between parental homes, or macroscale movements as they migrate between countries and cross international borders with their families or as independent travelers, child refugees, or workers. Children's geographies includes studies from across the globe but the Minority/Western world remains dominant in research, focus, and academic participation. This is reflected, for example, in the adult–child dichotomy which has been central to childhood studies but which is less central in situations where children have extended families, play a central role in the family economy, or take on parental responsibility due to parental HIV/AIDS, situations more commonly found in the global south (Punch and Tisdall, 2012). The Eurocentric dominant views of children, family, and space with their western notions of childhood innocence and dependency are being and need to be increasingly challenged if children's geographies is to be truly 'global' in orientation. In reality, as Skelton (2009: 1434) points out, "most of the world's children live in the economically poor countries of the Majority World." Although existing studies are dominated by western researchers, many of these researchers themselves are calling for a wider global remit for children's geographies.

Children's Rights

The UNCROC requires governments to respect and uphold children's rights in a range of areas from basic rights such as the right to a name, identity, life, and religion to more complex rights including the right to have a say in decisions that impact on their lives (article 12). In children's geographies, articles 12 and 13 (the right to access information) are especially important, as they emphasize the child's rights in matters that affect their lives, including matters relating to housing, environment, transport, leisure, access to schools, sports grounds, and health facilities. The progress of many countries toward fully implementing UNCROC has been slow, as illustrated by the fact that in 2008 one in three children in the UK lived in poverty and "disabled children continue to face barriers to the enjoyment of their rights, in particular access to appropriate health services, leisure and play" (UK Children's Commissioners, 2011). Recognition of children's rights across the world remains variable especially in countries experiencing political instability, war, and economic and environmental crises. Globally the position of children remains poor (Smith and Ansell, 2009). It is imperative that geographers recognize and prioritize giving voice to children's perspectives and views in their work.

The 'Universal' Child

There has been a tendency in traditional childhood studies and to some extent in children's geographies to talk of the child in a sense that implies a universal childhood, where identifying a 'child' as distinct to adult is seen as sufficient. More recently though recognition is being given to the fact that children lead highly diverse lives in often quite different social, political, geographic, and cultural contexts, where norms around behavior, age-appropriate activities, expectations, and so on can vary enormously (Hörschelmann and van Blerk, 2012). For

instance, in countries especially in the global south, children contribute to the family economy at a young age whereas in parts of the developed world young people commonly seek employment to fund their lifestyle choices. In other places it is seen as inappropriate for children to work. These types of differences can occur in different geographic locations, such as different countries, but can also be apparent in geographically similar but socially or economically different portions of society as in the same town. Within geographically close communities, children's lives can be markedly different depending on factors such as gender, family size, neighborhood, race, school attended, parental occupation or lack of, ability or disability, and so on. Some geographers have also investigated how differences in children's lives in terms of work/play balance are affected by global forces, and how the notion of a childhood based on play and school is not the norm for many of the world's children (Aitken et al., 2008). Growing international trade inequities and expansion of development in developing countries have led to increased pressure to engage in employment for children in many poor countries (Abebe, 2007).

Children reflect the diversity of the wider population in their experiences. To talk of children as a single entity masks the variability and indeed richness of their lives. Children can also act in multiple roles in different parts of and at different times in their lives. They may move between different cultural worlds that may have different languages. As they age, their physical abilities develop which enhances their ability to access places and to take up different social, economic, and cultural roles. Children's geographies needs to look beyond generic social and geographic boundaries, to the particular circumstances contributing to the child's position and identity. Disaggregation of children is particularly important if policy development is to recognize and accommodate children's diverse positions in society and their varied well-being. Recognition of difference is especially important in research.

Research

If research is to reflect accurately the reality of children's lives and perspectives, then the research must provide ways for the child's views and perspectives to emerge. There are a number of challenges that researchers face in this regard. As identified earlier, children are a highly heterogeneous and dynamic group whose lives are continually evolving as they age and develop. To enable children's knowledge to emerge, different research methods will be required to those used with adults, and special skills and techniques may be required in working with children. Some innovative work has been done in this regard using methods such as researcher observation, mental mapping, computer software programs such as softGIS, photo voice, walk along/go-along methods, child-focused interviews, and activities such as box city creation. The need for child- and age-appropriate methods is especially pertinent for working with very young children who are sorely underrepresented in research (see Hancock and Gillen, 2007 for an example of geographical research with preschool children).

Ethical considerations are important and more challenging than most adult-oriented research and relate to the need to ensure all children's best interests are fully protected. Ethical issues can and do arise during the research process as in disclosures by the child of matters of a harmful nature (e.g., neglect, exploitation) occurring in the child's own life. Such disclosures can cause the researcher to have to weigh up confidentiality against the need to act in a child's best interest. The researcher's own position, beliefs, and experiences also impact on the research process in which the researcher needs to be sensitive to the power differential present between adult and child and researcher and the child participant. Although research with children can be challenging, it is enlightening, fascinating, and often great fun for all involved. It is also potentially valuable for providing insights for researchers concerned with responses to major global challenges. The more active and engaging and fun the research process is, the better the data derived is likely to be.

Dominant Research Themes

An appreciation of the substance of children's geographies can be gleaned by looking at the broad range of themes it explores, including applications using different lenses (from positivist to postmodern and poststructuralist). The following list, by no means a complete one, indicates the breadth of coverage of research within children's geographies, including how children engage with the various spaces in their lives; health and hazards (traffic, pollution, inactivity, bullying); designing environments for children (including the concept of children as planners); children as citizens and social agents; children's cognitions/imaginings of their environment; exploitation of children, including child trafficking and slavery; the role of migration in children's lives; children and information technologies; and a lively and wide debate around the ethical issues involved in researching children. Many of these themes strongly interrelate with each other.

Rather than attempting to cover all the themes examined in children's geographies research, the focus here is on two broad themes that have attracted the attention of researchers within the subdiscipline:

1. studies of how children engage with the major spaces that they use in their daily lives (e.g., designated play space, schools, and the city center), particularly the way in which these spaces provide opportunities for children's play; and
2. research on the theme of children's mobilities (including active travel and independent mobility).

Children's Spatial Engagements

An important focus of children's geographies research involves children's perceptions of and engagement with key spaces in their daily lives. Children are portrayed as having an intimate connection with their local environments in ways that are qualitatively different from adult's connections. Largely through playful exploration, they have the ability to live in the present and be fascinated by their immediate surroundings, rather than being focused on a destination, and seeing the next task as more important than the present, as adults often do. Key spaces for children that have been

studied in children's geographies include playgrounds (Karsten, 2003), their own homes (Wood and Beck, 1994), streets (Fotel, 2009; Tranter and Doyle, 1996), school grounds (Dyment et al., 2009; Thomson, 2005), neighborhoods (Mee, 2010; Freeman, 2010), city centers (Woolley et al., 1999), and various service spaces other than playgrounds (ranging from community gardens, museums, hospitals to public markets) (Schmelzkopf, 1995; Watson, 2009).

The focus on these spaces occupied by children is partly a consequence of the progressive confinement of children to child-specific spaces, a trend beginning more than a century ago. The dominant view of children's place in western societies is centered on the home, family, private space and in the public domain to child-designated public spaces, predominantly playgrounds and skate parks. Children's access to public space has diminished, not least due to the dominance of a neoliberal policy agenda which has led to the winding back of public investment in cities, particularly in the UK, the US, Australia, and New Zealand. The erosion of investment in public space for children, as well as the commercialization of play spaces (McKendrick et al., 2000), has reinforced the view that children are illegitimate occupiers, or even troublemakers when occupying some 'adult' public spaces (Valentine, 2004).

A growing body of empirical studies has identified the need to consider the views of children themselves, and how they relate to their worlds in varied geographical settings. Children may be influenced by space, but they are not passive reactors; children can and do shape and influence both the social and physical nature of space. They create their own spaces in neighborhoods, school grounds, and public spaces in the city. They are in a state of continual negotiation with adults over space: where they can go, how they get there, whom they go with, and what they can do in those spaces. Children need to be mobile and to access space independently to develop. They have a strong need to explore, to encounter, to grow, and to engage with the world. They will attempt to pursue these needs passionately, vigorously, and autonomously, using their knowledge, understanding, and their social relationships to seek to promote their right to access the spaces that they need.

Playful Spaces

Play is often seen as the central business of childhood, and is the way that children learn about their world. Opportunities for play have been marginalized by a range of issues in society, from parental concerns about fast-tracking children's learning, to the loss of spaces for play and the exclusion of children from spaces regarded as 'adult' spaces. The contested notion of the play itself has attracted attention in children's geographies, warning against taking play for granted, and arguing that geographical studies are important in helping to define play as much as identifying the way in which children's play can contribute to the meanings of place (Harker, 2005).

Perhaps unsurprisingly, a great deal of children's geographies research has focused on playgrounds, as these are seen as a service space specifically designed for children. Geographic research has examined ways in which playgrounds are used by children, including children of different abilities, ages, and gender (Karsten, 2003; Moore et al., 1997). While this research is important, other geographic research has called into question the concept of special spaces for children, identifying the possibility that restricting children's play to playgrounds and school grounds may lead to 'childhood ghettoization' (Matthews, 1995: 223).

School

A research focus on schools (and school grounds) as a children's space is justified in terms of the centrality of schools to children's everyday life in many societies, their ubiquitous nature, the length of time spent in the school, and the way in which the various spaces and practices at the school, including a hidden curriculum, are critical in children's experience of both the inclusionary and exclusionary aspects of society (Collins and Coleman, 2008). Schools are not only spaces where children learn about an educational curriculum, but also spaces where they learn about societal structures, as reflected in the different quality of environments in rich versus poor neighborhoods. School grounds are particularly important for geographical research, as they allow the observation and analysis of key aspects of children's lives in a contained environment (Hemming, 2007). Key topics within school ground research include environmental learning in school grounds (Tranter and Malone, 2004), green school grounds (Dyment and Bell, 2007), physical activity, emotional geographies of pleasure, enjoyment, and playfulness (Bundy et al., 2009; Hemming, 2007), the loss of play opportunities as a consequence of a culture of risk aversion (Thomson, 2007), and the demonstration of social agency by children (Hemming, 2007).

City Center

Despite the city center being a potentially valuable site for children to engage with other people (including children) in public space, there has until recently been surprisingly little attention by geographers to this topic. This may reflect an underlying perception that children are out of place in the city center. Indeed, an Australian geographer, Fincher (2004: 337) became concerned by developers' attitudes to children in Melbourne: "… presentation of children … as burdensome – people from whom to 'escape' and 'be freed' … the construction of a myth that the perfect lifestyle is to be lived without children or other dependants – one's own or other people's." This argument has also been used to promote child-free gated communities, in some condominiums in the US, and adult tourism developments, and is implicit in elderly people's residential complexes even though children frequently visit relatives there. With the growing movement of families back into central city areas, interest in the lives of city children and the opportunities and constraints this environment offers has been the focus of renewed research in cities such as Auckland, New Zealand (Ergler et al., 2012) and Melbourne, Australia (Mizrachi and Whitzman, 2009). The reality of children's presence in the city centers confronts the widespread view that children's lives are focused on those spaces specially designated for children. While the city and the other spaces that provide important constituents of children's daily lives are important, so too is the ability of children to access these spaces, and hence mobility is a key theme in children's geographies.

Children's Mobilities

The term 'children's mobilities' has emerged only recently in children's geographies. It represents a combination of children's geographies with what has become known as the mobility 'turn' in the social sciences that emerged in the 1990s. The mobilities paradigm applies new theoretical approaches to understand the way that mobilities are "at the center of constellations of power, the creation of identities and the micro-geographies of everyday life" (Cresswell, 2011: 551). Children's geographies is now finding its way into journals about mobility, including the journal *Mobilities* (Barker et al., 2009), and special issues of the *Journal of Transport Geography* (Buliung et al., 2011). However, children's mobility is still developing its status in the transport/mobility field in geography. As Barker et al. (2009) point out only one paper in the first 3 years of the journal *Mobilities* focused specifically on children and young people. This relative neglect of children echoes the fact that children are a "user group that is poorly served by transport systems" in many cities (McMillan, 2005: 441), particularly in the US, Australia, Britain, and Canada.

Geographers were studying children's mobilities long before the 'new mobilities' paradigm (Sheller and Urry, 2006) emerged in the social sciences, though not with the same theoretical underpinnings. Colin Ward's (1978) *Child in the City* raised important questions about how children move around the city, and the stimulating experiences provided for children who were able to explore their city. A landmark quantitative study was the study by Hillman, Adams, and Whitelegg – *One false move: a study of children's independent mobility* (Hillman et al., 1990). This study of children's freedom of movement in cities was based on the various 'licences' parents give to their children, e.g., to cross roads alone, come home from school alone. The main findings of the research were that children's freedoms in England in 1990 were much lower than in 1971 (using data from the same schools in both years) and children in England in 1990 were much more restricted than children in similar cities in Germany. This pioneering study was replicated in cities in several countries, indicating considerable variability between nations, within cities, and between rural and urban areas (Collins and Kearns, 2001; Fotel and Thomsen, 2004; Tranter and Pawson, 2001). New data from a 2010 follow-up study of the Hillman et al. (1990) study showed that in 2010, German primary school children were still granted all the licences in greater proportions than their English counterparts, despite car travel to school in Germany rising to English levels (Shaw et al., 2013). As well as examining 'licences,' several different methodologies to study children's independent mobility have been employed by geographers, including qualitative research (e.g., using photography, guided walks) and quantitative approaches (e.g., travel diaries and spatial range analysis through the application of geographic information systems) (Tillberg Mattsson, 2002).

Geographers are also involved in research on resistance to the trend toward reduced independent mobility in western cities, examining the loss of children's freedoms in the context of changing expectations by parents, the growing dominance of private transport, and the possibilities for new arrangements (e.g., walking school buses) to regain some of the freedom for children (Kearns et al., 2003). Mobilities research has also incorporated the topic of play, focusing on both 'affect' and the concept of playful mobility (Tranter and Sharpe, 2012), suggesting that if children's mobilities involve playful activity, children will enjoy their mobility and adults will spend less time facilitating and supervising their children's physical activity.

As well as independent mobility, a related concept that has attracted the attention of geographers is that of children's 'active travel' – travel that involves some physical activity (walking, cycling, scootering, and public transport). While children's independent mobility and children's active travel are sometimes conflated, they are two separate concepts, and recent research has suggested that they should be viewed as distinct. Indeed, some of the health benefits believed to be associated with independent mobility can also be achieved with active travel supervised by adults (Mammen et al., 2012). The health and developmental benefits of active travel and independent mobility are now regarded as potentially more beneficial for children's health and development than organized sport and supervised exercise classes. Even the journey to school, if it can be made independently by children, allows them to develop a deeper understanding of the geography of their own neighborhoods and communities, as well as opportunities for free-play or day-dreaming – important activities for children (Ross, 2007).

New Directions for Children's Geographies

The search for new directions for children's geographies might well be guided by consideration of the changes in children's lives over recent decades, particularly for children in developed nations. These include a growing ethos of individualism; closure of local shops and schools; loss of wild spaces (natural spaces); increased population densities; increased pressure on children to compete in a consumerist world; replacement of children's independent mobility with adult-dependent mobility; increased use of technology for surveillance of children; more play indoors rather than outdoors; increased fear or risk aversion; and increasingly scheduled lives and an increased pace of life and time pressure. Many of these changes have impacts on adults as well as children, yet children have little choice but to accept and adapt to the changes. Many of the changes have led to a loss of opportunity for children to playfully explore their own neighborhoods and cities, and a concomitant increase in the pressures on parents to drive, accompany, or supervise their children's activities.

Importantly, many of these changes are driven by global forces. Children's lives are influenced not only by the global financial crisis, but also by other global trends and challenges. A growing global human population places increasing pressure on cities. A probable crisis in access to energy, particularly cheap oil (Brecha, 2013), is likely to have significant (if unpredictable) impacts on children's lives (Tranter and Sharpe, 2007). As Brecha (2013) argues, "being societally unprepared for declining oil production will have serious consequences." Climate change impacts on children are rarely forecast in a positive light (Bartlett, 2011). Many of these challenges are interdependent. For example, if a global response to a shortage of oil is to switch to liquid fuel from coal, this will very likely accelerate global climate change.

With few exceptions, children's geographies has been largely silent regarding these major global challenges and their potential impact on children. Here lies a valuable opportunity for new directions in the subdiscipline. Children's geographies needs to look not just at specific children in specific places (the microspaces discussed earlier), but at broader, global perspectives, considering the macroscale issues as they are influenced by "broad-brush political-economic and social-cultural transformations" Philo (2000: 253). Ansell (2009) reinforces this, arguing that "it is not *only* locally occurring processes, practices and events that impinge on children's lives. Economic globalization and neoliberal policies are transforming life for many young people, but they remain untouched by the small-scale participatory projects that are the focus of much research" (Ansell, 2009: 191). Geographers need to research and challenge the national and even global forces and processes that affect children. These include a neoliberal agenda in planning, the striving for economic growth that is clearly unsustainable, and a disregard for the likely impacts of energy stress and global warming.

If children's geographies are to be relevant, they need to be considered in spheres beyond those limited areas in which children's views are currently seen to be important and accepted (e.g., in the design of parks and playgrounds and leisure centers for children and young people). Virtually every aspect of city management and planning impacts directly or indirectly on children, whether it is housing, transport, education, health, or energy generation. Researchers within all these areas should be encouraged to consider children's interests. Article 3 of the UNCROC states: "The best interests of children must be the primary concern in making decisions that may affect them." Every decision made about any aspect of our economy, environment, and society ultimately affects children. An urgent need for a new direction in children's geographies is for a link to be provided between research on children's use of space and place and the *sustainability agenda* (Percy-Smith and Burns, ahead-of-print). Not only are children shaped by and in turn shape their worlds, but also their worlds are influenced by factors that operate from local to global scales. Future children's geographies may demonstrate that the views of children are vital in our responses to global challenges.

Abstract

In demography, the value of children refers most often to the benefits parents receive from having and rearing children. Benefits may accrue from the children themselves, from the experience of rearing them, or from the responses of kin, community, and society at large. Children also entail costs for parents and the value of children sometimes refers to their net value (benefits less costs). Benefits and costs of children are shaped by the economic conditions of life, forms of social organization, and cultural beliefs and practices. Studies using surveys to measure the value of children report variation in values across societies; by socioeconomic status; between women and men; for first, second, and higher order births; and for daughters versus sons. Cultural foundations for the value of children have also been explored. The net value of children underlies parents' desires for children which, in combination with their ability to achieve those desires, influences their decisions to have children and how many children they have.

Theoretical Development

Theories of fertility decline focus primarily on the economic value of children. In agricultural economies and during early periods of industrialization, parents and kin make the heavy investment of time and money in young children in order to reap the rewards of children's labor from adolescence onward (Schultz, 1973; Caldwell, 1976). The old-age security value of children is particularly important in contexts where no public provisions exist for elder care (Cain, 1985). For large numbers of people throughout the world, the economic value of children in the intermediate and long term continues to be a primary benefit of parenthood (Nauck and Klaus, 2007). Even in wealthy societies where children's labor is no longer central to their parents' subsistence, adult children may remain important to the economic well-being of elderly parents (Rendall and Bahchieva, 1998; Buehler, 2008).

Scholars have long recognized that the value of children extends beyond their direct economic benefits. The term 'value of children' is most closely associated with Hoffman and Hoffman (1973), who identified nine psychological needs fulfilled by parenthood and the experience of child-rearing: (1) adult status and social identity; (2) expansion of the self; (3) morality; (4) primary group ties, affiliation; (5) stimulation, novelty, fun; (6) creativity, accomplishment, competence; (7) power, influence, effectance; and (8) social comparison, competition. Most of these psychological needs have an inherently social character, an issue that becomes clear in subsequent theory and research.

Several scholars have attempted to develop a unifying theory of the value of children. Friedman et al. (1994) claim that the primary value of children is the reduction of uncertainty. Those with limited access to other means for uncertainty reduction, such as stable careers and marriages, will want to become parents. Few of the hypotheses derived from this theory stand up to empirical scrutiny, however, and those that do can be explained by the economic and social opportunity costs of children (Lehrer et al., 1996).

Building on the work of cultural anthropologists and sociologists, Schoen et al. (1997) propose that children produce social capital, i.e., social relationships and social resources. At birth, children strengthen parents' ties to kin. Through schooling and other activities, they link parents with community resources. As adolescents and young adults, children bring new information, ideas, and social relationships to parental households. And most parents eventually obtain in-laws and grandchildren as a consequence of parenthood. Although the social capital argument was developed in the context where children have low or no economic value, it may have more general applicability. Where family, kin, and community ties provide economic opportunities and security, the social capital produced by children may be as economically valuable as their labor or accumulated wealth. Buehler (2008) makes a similar argument that parenthood is motivated by what he terms the 'structural value' of children, i.e., the expansion of personal networks and exchange relationships arising from the birth of a child. These networks and relationships produce in turn psychological rewards (Hoffman and Hoffman, 1973) and social capital (Schoen et al., 1997). But the extent to which the personal networks and exchange relationships are activated for the parents' well-being depends on the quality of the parent–child relationship.

Nauck (2007) derives the value of children from a general theory of social production functions in which individuals seek to maximize physical well-being and social esteem. Physical well-being requires comfort and stimulation; social esteem requires status, affect, and behavioral confirmation. The value of children is based on the extent to which children enable parents to achieve these five intermediate goals. The nature of the parent–child relationship means that stimulation, affect, and behavioral confirmation are confounded. The theoretically derived value of children is thus organized along lines identified by others – economic (comfort), social (status), and psychological (stimulation, affect, behavioral confirmation).

Children are also quite costly to their parents during the child-rearing years. Fertility declines in the twentieth century have been attributed in large part to declines in the economic value and increases in the economic costs of children to their parents (e.g., Caldwell, 1976). Most theorists distinguish

between the direct costs of children (food, clothing, shelter, education, etc.) and the opportunity costs of childcare for the parents' alternative activities (Fawcett, 1978). Parents also incur social and psychological costs from their responsibilities for and interactions with children (Hoffman and Hoffman, 1973; Fawcett, 1978; Schoen et al., 1997; Buehler, 2008).

Measuring the Value of Children

The Value of Children (VOC) surveys conducted in the mid-1970s (Fawcett, 1983) were based on the social psychological values developed by Hoffman and Hoffman (1973), but also contained information on the perceived economic benefits as well as the psychological, social, and economic costs of children. Respondents were asked open-ended questions about reasons for having or not having children and were asked to rate the importance of several lists of child benefits and costs as reasons to have or not have children or their next child. Most subsequent empirical research was based on closed-format questions. A partial replication of the VOC in the early 2000s (Nauck and Klaus, 2007) extended the importance scale from three to five points, improving the measures' reliability and validity. Seven-point importance ratings were used in the U.S. National Survey of Families and Households (Seccombe, 1991).

Subjective-expected-utility or expectancy-value models (e.g., Davidson and Jaccard, 1975) specify child benefits and costs as the product of the likelihood that having a child will produce a given outcome and the value (positive or negative) of the outcome. Each perceived likelihood and value is measured on a scale with several response options. More recent research in this tradition attempts to measure the combination of value and likelihood with a single response, e.g., agreement with a statement about positive or negative outcomes (Billari et al., 2009; but see Liefbroer, 2005).

Measurement analyses of child benefits and costs generally confirm the theoretical clusters of economic, social, and psychological well-being (Schoen et al., 1997; Nauck and Klaus, 2007), or at least separate the economic from the social and psychological (Mayer and Trommsdorff, 2010). Perceived costs constitute a separate dimension (Nauck and Klaus, 2007; Billari et al., 2009). Benefits and costs of children may also be distinguished in relation to general theories of fertility and fertility change (Liefbroer, 2005).

The real as opposed to perceived economic benefits and costs of children can also be measured indirectly based on the value of children's labor and transfers to parents over the life course, expenditures related to child-rearing, and the value of parental time that might otherwise be spent on income-producing activities (e.g., Rosenzweig, 1978). DiPrete et al. (2003) used a combination of time-budget data, attitude data, and estimates of the effects of a birth on labor earnings and standard of living changes to compare the economic costs – direct and opportunity – of children in different countries. In the aggregate, costs were strongly associated with national fertility rates. Zelizer (1985) argued that in a context where children's net economic value is zero, monetary compensation for a child's death represents children's net socioemotional value.

Variations in the Value of Children

The Value of First- and Later-Born Children

The original Value of Children studies found that first-, second-, and higher order births are associated with distinct benefits and costs (Bulatao, 1981; Fawcett, 1983). The first child confers the status of parenthood, so that benefits associated with parenthood per se can be acquired by having only one child. Adult status, relationship stability, parent–child interaction, and kin connections are all cited as primary reasons for becoming a parent. The first child is also associated with the greatest increase in opportunity costs, that is, constraints on parental time and energy.

The most important value of a second child is to provide a sibling for the first (Bulatao, 1981), a value that could be incorporated into the social dimension of child value discussed above. The value of higher order births may be predominantly economic – each child contributes additional labor or economic security for parents – but could also further strengthen partnership and kin ties and provide additional opportunities for rewarding parent–child interactions.

Griffith et al. (1985) pointed out that some of the unique values of first and second births may apply to the parity of a couple, independent of each partner's parity. She argued that the value of a child as a representation of the couple's commitment to one another would be relevant in stepfamilies, even when one or the other partner already had a child. The couple-specific value is argued to underlie the larger combined family sizes of step-family couples in comparison to couples in stable partnerships (Thomson, 2004).

Each child also adds to the parents' child-rearing costs, including direct financial expenditures and limitations on alternative uses of time. It appears, however, that cost considerations remain relatively stable across parities due to a trade off between quantity and quality (Bulatao, 1981; Nauck, 2007). That is, parents with small numbers of children may invest more time and money in each child than parents with larger numbers of children.

Gender and the Value of Children

Overall, men and women perceive the values and costs associated with children in much the same way. The few differences that are observed are consistent with traditional gender roles (Fawcett, 1983; Seccombe, 1991; Buehler, 2008). Liefbroer (2005) found that gender differences arose primarily from differential likelihood of outcomes for men and women, not the relative value of those outcomes. Men are, on average, more concerned than women about the financial costs of child-rearing and in patrilineal societies about having sons to continue the family name. Women place greater importance than do men on the work and strain of raising children, and in some cases also the opportunity costs of children for other activities, and the benefits of children for the marital relationship (Fawcett, 1983).

Differences in the perceived benefits of daughters and sons are also related to differences in the roles and behaviors of men and women (Fawcett, 1983). In patrilineal societies, sons are valued more than daughters for kinship ties, that is, to continue the family name. Where men have greater access than women

to economic opportunities, sons may also be valued for future financial assistance. Daughters are valued more than sons for household and childcare help and companionship. In patrilineal societies, the values associated with sons are produced for the most part in adulthood, those associated with daughters during childhood, consistent with the practice of daughters' leaving the parental home upon marriage. Many of the benefits of children, particularly social and psychological benefits, do not appear to differ for sons and daughters. Thus, where children provide few economic benefits, few parents express preferences for sons versus daughters, but rather prefer at least one of each (Hank, 2007).

Socioeconomic Variation in the Value of Children

As noted above, the economic value of children is associated with agricultural and household economic production and the absence of social insurance for elderly parents. Although children also entail high economic costs in such contexts, they are necessary for survival. Industrialization and urbanization reduce the economic value of child labor and increase the costs of rearing children to be economically independent. Economic development eventually leads to the development of social insurance that reduces further the economic value of children for support in old age. As a result, children's net economic value is perceived to be lower in industrialized wealthy countries than in poorer countries with a greater dependence on agricultural and household production (Fawcett, 1983; Nauck and Klaus, 2007), except for those at the bottom of the economic ladder in wealthy countries (Rendall and Bahchieva, 1998).

Psychological benefits and costs of children were reported in the original VOC surveys to be more important in industrial and postindustrial settings than in agricultural settings (Fawcett, 1983). This difference could arise because of the priority of economic survival over psychological well-being (Zelizer, 1985). Children may provide psychological benefits (and costs) for parents in all settings, but these components of child value become salient only when children become irrelevant to economic survival. The more recent VOC surveys find no difference across societies at different levels of economic development in the emotional value of children (Nauck and Klaus, 2007; Mayer and Trommsdorff, 2010).

Because the social capital or social esteem value of children has only recently been introduced into theoretical discussions of the value of children, it is difficult to know how such values might vary under different economic conditions. In agricultural settings, there may be a stronger association between economic and social ties so that the latter are not distinguishable from the former. Only in industrial and urban societies may social capital be sufficiently separable from financial capital to identify it as a separate source of child value.

Socioeconomic variation in the value of children is also evidenced across families within societies (Fawcett, 1983). A consistent finding from VOC surveys was that urban respondents place a lower economic value and a higher emotional value on children than do respondents living in rural areas. Similarly, education is inversely associated with children's economic value and directly associated with their emotional value as well as with perceived restrictions or opportunity costs of parenthood. Direct financial costs and childcare stresses do not vary substantially across countries or across individuals in different economic circumstances, likely due to the greater investments parents of higher socioeconomic status make in each child. Although one might expect the opportunity costs for mother's employment to increase with socioeconomic status, well-paid mothers can purchase substitute care. Klein and Eckhard (2007) found no differences in the perceived opportunity costs of children or in their effects on childbearing across socioeconomic levels.

Culture and the Value of Children

Broad cultural values may also serve as sources of specific or general values of children. Religious institutions and beliefs may support the value of children for social and psychological benefits. For example, Catholicism is viewed as a support for large-family values in the Philippines, Confucianism for the high value of sons to carry on the family name in some Asian countries. The relative values of daughters and sons are associated with broad cultural values on gender equality (Fawcett, 1983).

Lesthaeghe (1983) argues that ideational change is an independent force underlying current low fertility in Western countries. He identifies the two most salient features of this change as secularization and individuation. Secularization allows more latitude to individual morality; individuation stresses the importance of personal self-actualization. Using national surveys of social and family values, Lesthaeghe and colleagues (e.g., Lesthaeghe and Meekers, 1986) distinguish two dimensions of family values – a nonconformity dimension linked to partner relationships and nonmarital childbearing; and the 'meaning of parenthood,' including beliefs that children are necessary for fulfillment and for marital success. Measures of secularism and individuation were strongly associated with nonconforming family values, but only weakly associated with the meaning of parenthood.

This finding is consistent with the argument of Ehrhardt and Kohli (2011) who distinguish two dimensions of individualization. The first dimension, an increase in status of the individual – particularly children and women – underlies the decreased economic value and increased economic costs of children, including opportunity costs for their mother's employment. The second dimension, an increase in autonomy and freedom of choice, does not imply an increased competition between self-actualization and parenthood. It does underlie, however, dramatic decreases in union stability and the economic safety net for mothers and children, operating not through children's social and psychological benefits but through their economic costs.

The Value of Children and Fertility

Hoffman and Hoffman (1973) theorized that the influence of psychological needs met by parenthood or by particular numbers of children would depend on the intensity of such needs and the availability of alternative mechanisms for fulfilling them. Studies using ratings such as those in the VOC surveys have generally found that high perceived economic

benefits of children are associated with a large family size. The importance of psychological benefits and restrictions on parental activities are associated with a small family size (Fawcett, 1983; Nauck, 2007; Mayer and Trommsdorff, 2010). The relationship between perceived child values and fertility is not, however, as strong as some scholars had hoped, and the financial and time/effort costs of children are not associated with family size (Fawcett, 1983; Nauck, 2007).

Relatively moderate associations between values of children and completed fertility should not be surprising. As noted above, many child values may be parity specific and should be expected to influence only specific parity progressions. Further, child values can influence only desired fertility, so that the relationship between values and outcomes depends on the degree of fertility control. In addition, early measures of the perceived value of children were relatively crude (e.g., three-point response scale). When a particular parity progression is specified, when contraception is pervasive, and when precise measures of the expected value (net of cost) of children are generated, much stronger associations are observed between values and births (e.g., Liefbroer, 2005; Nauck, 2007).

Nauck (2007) argues further that fertility decision-making is likely to be rational – considering carefully the benefits and costs – primarily during a period of fertility transition. Before and after the transition, when most people share an understanding of children's values and costs, decision-making will be more routinized and spontaneous, thus more strongly influenced by prevailing social norms.

China as a Rising Aid Donor

Shino Watanabe, Sophia University, Tokyo, Japan

© 2015 Elsevier Ltd. All rights reserved.

Abstract

China's foreign aid dates back to 1950. With a history of more than six decades, China has become one of the most important emerging donors. This article provided a comprehensive overview of China's foreign aid from the following perspectives: terms and definitions, aid modalities and volumes, aid projects, distribution and allocation, decision making, management, aid procedures, and major characteristics. It then analyzes China's contributions and challenges to international society.

Introduction

Since the late 1990s, the People's Republic of China (China) has been expanding its presence in many significant ways. Foreign aid is not an exception. China has been treated as one of the most important rising donors, along with other BRICS countries namely, Brazil, Russia, India, and South Africa. However, it is misleading to assume that rising donors are monolithic and regard China as a typical one (Manning, 2006; Sato et al., 2011; Rowlands, 2012). They are heterogeneous with their distinct characteristics, although some commonalities exist.

China's foreign aid dates back to 1950, not even a year after China was established in October 1949, meaning it has a history of more than 60 years as a donor. China's foreign aid has a far longer history than many other rising donors, with the exception of Russia and India. At the same time, China was a recipient of foreign aid at the outset of its establishment in 1949. Therefore, China's foreign aid has been shaped through its unique experience of simultaneously being a recipient as well as a donor (Watanabe, 2012b).

China's foreign aid is not necessarily well known despite such significance. The Chinese government has not disclosed detailed information on its foreign aid. In April 2011, China first published its white paper on foreign aid. Since then we have come to see some concrete and official information on China's foreign aid. Accordingly, the literature on China's foreign aid is slowly emerging not only in English but also in other languages, including Chinese and Japanese.

Building upon such growing literature, this article seeks to provide a brief but comprehensive overview of China's foreign aid. First, it deals with the thorny issue of terminologies and definitions related to China's foreign aid. It examines what is to be considered China's foreign aid. Second, it provides an overview of China's foreign aid based upon the first white paper. Third, it identifies major characteristics of China's foreign aid, in order to highlight the differences between China's foreign aid and those offered by major traditional Development Assistance Committee (DAC) donors. Fourth, it analyzes the major contributions and challenges of China's foreign aid. Finally, conclusions and some observations are provided.

Terms and Definitions

First and foremost, we should note that China's foreign aid is an ambiguous concept. China has been reluctant to call itself a donor or its efforts toward foreign countries as foreign aid. This is partly because China has been sensitive to the hierarchical relationship that would be implied by using these terms. China prefers to describe itself as a partner and use more mutual terms such as 'economic cooperation', 'development cooperation', and 'development assistance' (King, 2006).

China is willing to emphasize its partnership among developing countries. For many developing countries, the term 'donor' is often associated with concepts such as paternalism, hierarchy, and neocolonial interference; hence, they favor the term, 'development partners', indicating a horizontal relationship that deserves mutual benefits, noninterference, and respect for sovereignty (Mawdsley, 2012).

Therefore, it is no surprise that no official definition of foreign aid exists in China in a way that could be compatible with Official Development Assistance (ODA) of DAC within the Organization for Economic Cooperation and Development (OECD). DAC, a committee established within OECD, serves as a platform of traditional Western donors to promote primarily appropriate and desirable aid practices, enhances coordination among member donors, and monitors members' aid policies and practices.

In 1972, DAC defined ODA as those flows to countries and territories on DAC's List of ODA Recipients (www.oecd.org/dac/stats/daclist) and to multilateral institutions that are: (1) provided by official agencies, including state and local governments, or by their executive agencies and (2) each transaction of which (a) is administered with the promotion of the economic development and welfare of developing countries as its main objective and (b) is concessional in character and conveys a grant element of at least 25% (calculated at a rate of discount of 10%).

Meanwhile, rising donors define their foreign aid in their own ways. Obviously China's foreign aid does not conform to the ODA. From the outset, China has offered foreign aid based upon its own criteria and has not considered it under the category of ODA. Thus, it is misleading to call China's foreign aid ODA, although there is no publicly available definition of China's foreign aid (Davies, 2007). Even China's first white paper on foreign aid did not provide any official definition of China's foreign aid in a manner equivalent to DAC's definition (Information Office, 2011). It merely identified three categories of China's foreign aid: grants, interest-free loans, and concessional loans.

As a matter of fact, China's foreign aid is much broader than what is constituted as ODA. Although China's foreign aid does

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64130-2

include some efforts equivalent to ODA, it also embraces other transactions that would be classified under the Official Development Finance, namely, concessional loans that cannot satisfy the concessional terms of ODA (Brautigam, 2010). In other words, ODA equivalency alone is insufficient for understanding China's entire aid activity. The common wisdom is that Chinese government–sponsored investment activities are an integral part of its foreign aid and should be considered as such (Brautigam, 2009, 2010; Wolf et al., 2013).

Overview of China's Foreign Aid

Aid Modalities and Volumes

China's foreign aid falls in three categories: grants, interest-free loans, and concessional loans. Grants and interest-free loans are provided from China's state finances. Concessional loans are offered by the Export-Import Bank of China (ExIm Bank). China had offered 256.29 billion yuan in aid from 1950 to the end of 2009, including 106.2 billion yuan in grants, 76.54 billion yuan in interest-free loans, and 73.55 billion yuan in concessional loans (Information Office, 2011).

Grants are a sum of money given by the Chinese government for specific purposes, such as building social infrastructure (hospitals, schools, low-cost houses, and well and water-supply projects, among others) and implementing social welfare projects. Grants are also spent for small- and medium-size projects for human resource development, technical cooperation, and humanitarian assistance (Information Office, 2011).

Interest-free loans are mainly offered to developing countries that are economically solvent. They are used to build public facilities and implement projects that improve people's livelihoods. According to the white paper, interest-free loans last 20 years: 5 years of use, 5 years of grace, and 10 years of repayment (Information Office, 2011).

Concessional loans are the most prioritized modality in China today. They are offered mainly to finance infrastructure projects. The ExIm Bank uses the money it raises on the market as principal but can extend concessional loans with relatively low rates, as the Chinese government offers financial subsidies to the bank. According to the white paper, China's concessional loans are 15–20 years long, including a 5- to 7-year grace period, and the annual interest rate is between 2 and 3%. By the end of 2009, China had extended concessional loans to 76 countries and assisted 325 projects (Information Office, 2011).

With the exception of the figures disclosed in the first white paper, China's foreign aid still includes many unknowns. According to Wolf et al. (2013), China's aid pledges expanded dramatically – from $1.7 billion in 2001 to $189 billion in 2011 – for two reasons. First, China has accumulated a massive current account surplus and, hence has been plowed back into international society by way of foreign assistance. Second, China needs to secure a stable supply of natural resources to maintain its rapid economic growth. Foreign aid and government-sponsored investment are effective tools for enabling China to satisfy such needs. In contrast, they estimate that the annual average of aid delivered by China was $6.3 billion from 2000 to 2010 and while cumulative deliveries were $50 billion up to 2010, just 9.4% of China's total pledge (Wolf et al., 2013). The gap indicates that China's aid pledge has yet to be accepted at face value.

Aid Projects

China's foreign aid takes the following eight forms: complete projects, goods and materials, technical cooperation, human resource development cooperation, medical teams sent abroad, emergency humanitarian aid, volunteer programs in foreign countries, and debt relief.

Complete projects are conducted in production and people's livelihood in the fields of industry, agriculture, culture and education, health care, communication, power supply, energy, and transportation, either with grants or interest-free loans. They originated in China's foreign aid to Vietnam and the Democratic Republic of Korea (North Korea) for reconstruction and economic development in the 1950s. By the end of 2009, China had assisted with more than 2000 complete projects. Complete projects today are a major form of China's foreign aid and account for 40% of its aid expenditure (Information Office, 2011).

Goods and materials were the initial form of China's foreign aid and were offered for free. China provided a variety of goods and materials to recipient countries: machinery, equipment, medical devices, testing equipment, transport vehicles (including civil airplanes, locomotives, and container-testing equipment), office equipment, food and medicine, and so forth (Information Office, 2011).

Technical cooperation takes the form of sending Chinese experts in a variety of fields to enhance the self-development capacity of recipient countries. The fields include industrial production and management, farming and poultry raising, handicrafts, culture and education, sports and physical training, medical and health care, clean energy development, geological survey and prospecting, and economic planning. Even after complete projects are constructed, China trains people on production, operation, and maintenance of complete projects by means of technical cooperation. Such cooperation generally takes 1–2 years, with extensions possible based on requests from recipients (Information Office, 2011).

Human resource development cooperation takes the form of various training programs for experts and workers in recipient countries. It started in 1953, and by 1979, China had invited many trainees from foreign countries including North Korea, Vietnam, Albania, Cuba, and Egypt. In 1981, China began to offer practical training courses in developing countries in cooperation with the United Nations Development Program. In 1998, China started to offer seminars for government officials, and the programs extended to cover a variety of fields. China had trained more than 120 000 people by the end of 2009, covering more than 20 fields including economics, diplomacy, agriculture, medical and health care, and environmental protection. Today, China offers training for 10 000 people from developing countries annually (Information Office, 2011).

China first sent a team of medical doctors and nurses to Algeria in 1963 and has since sent medical teams to 69

developing countries in Asia, Africa, Europe, Latin America, the Caribbean, and Oceania. The teams not only offered medical services but also provided medical devices and medicines for free. By the end of 2009, China had sent more than 21 000 medical workers abroad, who have treated 260 000 million patients in developing countries (Information Office, 2011).

China offers emergency humanitarian aid to countries suffering from natural disasters in the forms of cash, materials, or dispatched personnel. In September 2004, China officially developed a response mechanism for emergency humanitarian relief and aid. China has provided emergency humanitarian aid to countries in many occasions, including bird flu in South Asian countries; a locust plague and cholera in Guinea-Bissau; dengue fever in Ecuador; H1N1 influenza in Mexico; serious earthquakes in Iran, Pakistan, Haiti, and Chile; a hurricane in Madagascar; tropical storms in Burma and Cuba; and a flood in Pakistan. China has also offered emergency food aid to many of the least developed countries, such as North Korea, Bangladesh, Nepal, Afghanistan, Burundi, Lesotho, Zimbabwe, and Mozambique (Information Office, 2011).

China began overseas volunteer programs by sending volunteers to developing countries in May 2002 and volunteer Chinese language teachers in 2003. The first country to which China dispatched volunteers was Laos. By the end of 2009, China had sent 405 young volunteers to 19 countries including Thailand, Ethiopia, Laos, Myanmar, Seychelles, Liberia, and Guyana. These volunteers served the local people in many ways, such as Chinese language teaching, traditional Chinese medicine treatment, agricultural technology, sports and physical training, computer skills, and international relief. China had dispatched 7590 Chinese language teachers to more than 70 countries by the end of 2009 (Information Office, 2011).

Finally, China has occasionally canceled its mature interest-free government loans for heavily indebted poor countries or least developed countries. China first announced such debt relief at the First Forum on China–Africa Cooperation (FOCAC) Ministerial Conference in 2000; it has since made similar announcements on other occasions, including the UN High-Level Meeting on Financing for Development in 2005, Beijing Summit of the FOCAC in 2006, UN High-Level Meeting on the Millennium Development Goals in 2008, FOCAC Fourth Ministerial Conference in 2009, and UN High-Level Meeting on the Millennium Development Goals in 2010. By the end of 2009, China had canceled 380 mature debts worth 25.58 billion yuan for 50 countries in Africa, Asia, Latin America, the Caribbean, and Oceania (Information Office, 2011).

Distribution and Allocation

The first white paper disclosed some information on the distribution of China's foreign aid. China has offered its foreign aid to 161 countries, including most of the developing countries by the end of 2009. Among them, 123 developing countries have consistently received foreign assistance from China, including 51 countries in Africa, 30 in Asia, 18 in Latin America and the Caribbean, 12 in Oceania, and 12 in Eastern Europe (Information Office, 2011).

The sector allocation of the concessional loans was as follows: 61.0% for economic infrastructure (transportation, communications, and electricity infrastructure), 16.1% for industry, 8.9% for energy and resources development (such as oil and minerals), 4.3% for agriculture, 3.2% for public facilities, and 6.5% for others areas (Information Office, 2011).

China prioritizes agriculture, rural development, and poverty reduction in recipient countries today. As such, its foreign aid covers a variety of fields: agriculture, industry, economic infrastructure, public facilities, education, and medical and health care, among others.

China's foreign assistance in agriculture includes (1) building farms, agrotechnology demonstration centers, and experiment and promotion stations of agrotechnology; (2) providing irrigation and implementing water-conservancy projects; (3) offering agricultural machinery and implements, farm produce processing equipment, and related agricultural materials; (4) sending experts to share agricultural production technologies and advice on rural development; and (5) training agricultural personnel (Information Office, 2011: p. 15). China had assisted 221 agricultural projects more specifically, 35 farms, 47 agrotechnology experiment and promotion stations, 11 animal husbandry projects, 15 fisheries projects, 47 farmland irrigation and water-conservancy projects, and 66 other types of agricultural projects (Information Office, 2011).

Industrial aid has been a major tool for China particularly from the 1950s to 1970s, and it assisted recipient countries to build the foundation for industrial development. In the 1970s, industrial aid was an important part of China's complete project aid. China had implemented 688 industrial production projects by the end of 2009 and assisted building many industries, such as light, textile, machinery, chemical, metallurgical, electronic, construction materials, and energy industries (Information Office, 2011).

Economic infrastructure has been an important sector of China's foreign aid. China had implemented 442 projects for economic infrastructure by the end of 2009. China has contributed to facilitating economic and social development in recipient countries by assisting in building economic infrastructure (Information Office, 2011).

China has also assisted recipient countries by building public facilities, such as civilian buildings, wells for water supply, conference centers, sports venues, culture venues, and facilities for scientific, educational, and medical care purposes (Information Office, 2011). China had built 687 public facilities in recipient countries by the end of 2009.

China has emphasized its foreign aid in education, particularly by building schools, offering teaching equipment and materials, sending teachers, training teachers and interns from other developing countries, and offering government scholarships to students from other developing countries to study in China. By the end of 2009, China had built more than 130 schools and offered funding for 70 627 students from 119 developing countries. China has built hospitals and medical care centers as well as malaria prevention and treatment centers, sent medical teams, trained medical workers, and provided medicines and other medical materials. China had built more than 100 hospitals and medical care centers by the end of 2009 (Information Office, 2011).

China has offered foreign aid in clean energy and coping with climate change for several decades. For instance, China assisted recipient countries in building small- and medium-size

hydropower stations and projects of power transmission and offered training courses on clean energy sources and climate change. China had held 50 workshops on the development and use of renewable resources, forestry management, and desertification treatment and prevention for more than 1400 people from developing countries. China had also offered biogas technologies to recipient countries to diversify their energy sources (Information Office, 2011).

Decision Making, Management, and Aid Procedure

It is unclear how China's foreign aid policy is determined. It seems that the top level determines the policy direction and budget allocation, working with the Chinese Communist Party's Leading Group and the State Council (IDRC, 2007). A State Council subgroup decides all foreign aid projects (Davies, 2007). The administrative department of foreign aid in China is the Ministry of Commerce (MOFCOM), which is responsible for foreign aid funds and is in charge of formulating foreign aid policies, regulations, and plans, examining and approving aid projects, and managing project execution. MOFCOM also engages in the tendering process and actual operations. The Executive Bureau of International Economic Cooperation, China International Center for Economic and Technical Exchanges, and Academy of International Business Officials – all affiliated with MOFCOM – oversee management of the implementation of complete projects and technical cooperation projects. The ExIm Bank is responsible for project assessment, allocation, and recovery of concessional loans (Information Office, 2011).

Meanwhile, MOFCOM communicates with the Ministry of Foreign Affairs (MOFA), Ministry of Finance (MOF), and the ExIm Bank when it drafts foreign aid programs and funds plans for each country. Other relevant government agencies also participate in the management of foreign aid programs based upon their expertise. In 2008, MOFCOM, MOFA, and MOF established a foreign aid interagency liaison mechanism to enhance coordination. It was developed into an interagency coordination mechanism in February 2011 (Information Office, 2011).

China's foreign aid takes the following procedure. First, the recipient government submits a loan application to the ExIm Bank. If the bank approves the application, it is forwarded to MOFCOM, and MOFCOM concludes a framework agreement with the recipient country (Davies, 2007). The bank then concludes a project loan agreement with the recipient. Because the loan is tied, Chinese contractors engage in the construction of the financed infrastructure projects (Kjollesdal and Welle-Strand, 2010).

Foreign Aid with Chinese Characteristics

China has favored the label 'South–South cooperation', and considers its foreign aid under this framework. This means that both China and the recipient countries are South, and are equal partners, which creates several distinctive characteristics of China's foreign aid.

First, China has been highly sensitive to the hierarchical relationship between donors and recipients. This might reflect China's long history of being recipients of foreign aid. China portrays itself as a developing country and thus advocates such principles as equality, mutual benefits, and mutual development between donors and recipients. Put more directly, national interests – not only political but also economic – are the main drive for China's providing foreign aid. In recent years, China has sought to increase its exports to and investment in recipient countries, secure access to raw materials and energy resources, and gain support from and political influence over recipient countries.

Second, South–South cooperation indicates that China is still a developing country, similar to the recipient countries. This means that China shares common problems that have been caused by the process of development in other developing countries. Of course, traditional donors do have experiences that could be applicable to developing countries as well. Because China is at a relatively similar stage of development, it has been dealing with impediments of development. Thus, China is more likely to have recent and firsthand experience in achieving economic development and realistic and effective solutions for many problems that developing countries might be able to apply. For China, foreign aid is one of the useful mechanisms for sharing its direct experience with other developing countries; for recipient countries, it makes the China model all the more appealing and easier to follow than those of advanced Western countries.

Yet, we should note that there is still no consensus as to what exactly constitutes the China model. In 2004, Joshua Cooper Ramo coined the phrase 'Beijing Consensus' as opposed to 'Washington Consensus' to describe China's development model that emphasizes political factors including a state-led initiative for economic development and self-determination (Ramo, 2004). Discussions and debates both inside and outside China have examined what constitutes the China model (Halper, 2010).

Third, China opposes the imposition of any political conditions in providing foreign aid. Based upon its Five Principles of Peaceful Coexistence (mutual respect for sovereignty and territorial integrity, mutual nonaggression, noninterference in each other's internal affairs, equality and mutual benefit, and peaceful coexistence), China perceives that imposing conditions on recipients involves an intervention into their internal affairs and, hence, rejects the idea of conditionality.

Traditional DAC donors tend to impose some kind of conditionality when they offer foreign aid. Aid conditionality basically takes some of the following forms: budget cut, small government, liberalization of foreign exchange and trade, deregulation, democratization, and good governance. They reflect the common belief shared among most of the aid community – namely, the Washington Consensus – based upon neoclassical economics. This belief implies that developing countries should follow certain paths for development – more specifically, those Western donors experienced in the process of their development.

In contrast, China respects the right of recipient countries to manage their own development paths. Based on its own experience of achieving dramatic economic growth over the last three decades by implementing its Open and Reform Policy and learning through trial and error, China appreciates the freedom of choosing its own development path suitable to its actual conditions. Thus, China advocates for the existence of

multiple paths for development, one of which is undoubtedly the China model.

Although China is less enamored with conditionality, it has requested that recipient countries adhere to the One-China policy rule: China offers foreign aid to countries that have diplomatic relations only with China, not Taiwan. For recipient countries, this rule would be a semi-conditionality in receiving China's foreign aid.

Major Impacts of China's Foreign Aid

China's different administrative norms and practices in its aid operation have produced mixed impacts not only for the donor community, but also for recipient countries. China's growing aid is undoubtedly a welcome engagement to international society.

First, as a rising donor, China has contributed to increasing the total amount of foreign aid flowing from donors to developing countries. By the end of 2009, China's foreign aid had reached most of the world, covering 161 countries and regions. In addition, China increased its budget for foreign aid by 29.4% annually between 2004 and 2009 (Information Office, 2011). Major DAC donors are still suffering from the negative repercussions stemming from the Lehman Brothers crisis in 2008, including economic downturn and high unemployment, and hence have difficulties in boosting budgets for foreign aid significantly. Thus, with its growing economy, China is a promising donor.

Second, China's manner of aid giving offers some strengths. China's swift decision making due to the top-down mechanism of the Chinese Communist Party and quick implementation of aid projects has been highly appreciated by recipient countries. Moreover, China has provided new aid modalities and ideas of development. Based upon recipient countries' growing need for capacity development, China continuously enriches its soft aid type cooperation in terms of human resource development, sending medical teams and experts oversees, not just expanding its hardware type assistance. China's resource-backed financing, the so-called Angola mode is another example. It is a mechanism through which China extends loans in return for resources, for instance oil in the case of Angola. Without such an arrangement, it would be impossible to receive foreign loans.

Meanwhile, the negative side of the ledger is also significant, causing several concerns. China's unique style of foreign aid challenges standardized foreign aid practices, which have been shaped through the international donor community, particularly among DAC donors. China's 'no strings attached' policy has been criticized for several reasons, such as postponing the necessary reform (both democratic and administrative), hindering the improvement of transparency and accountability, and undermining Western donors' leverage for enforcing policy reform in recipient countries. In other words, China's foreign aid offers a loophole to some of its recipient countries to circumvent conditionality that they would otherwise have to address (Manning, 2006).

Tying status is another critical problem. China's concessional loans are all tied as China requests that recipients of its concessional loans procure more than 50% of goods and services from China. This idea contradicts the existing norm of traditional donors, however. In 2001, DAC came up with a formal recommendation that aid for the least developed countries should be untied. Tied aid is perceived to undermine the effect of aid projects in recipient countries. A study by the World Bank pointed out that tied aid is costly to recipient countries, degrading the value of aid by about 25% (World Bank, 1998).

Last but not least, China's foreign aid projects have caused a variety of problems in recipient countries. Although we do not naïvely buy all the stories of problems related to China's foreign aid projects overseas that have been widely covered by media reports, it is true that China's foreign aid sometimes causes problems in recipient countries. China's emphasis on implementing economic infrastructure projects is more prone to corruption and political scandals than other types of foreign assistance. The behavior of Chinese companies and workers has caused various concerns. Chinese workers on China's foreign aid projects sometimes create tension in local communities as the projects do not create new employment opportunities for local people. The poor and severe labor conditions of Chinese workers scare the local community. In addition, some of the facilities and infrastructure constructed by Chinese companies are inferior in quality.

Conclusions and Observations

China is still an emerging donor. It is currently unrealistic to assume that China, in cooperation with other rising donors like BRICS countries as a bloc, challenges DAC by posing an alternative to the existing aid architecture. China's foreign aid has yet to become a substitute to the existing aid architecture (Rowlands, 2012).

Meanwhile the presence of emerging donors still has important implications for the current aid architecture. DAC's long-term efforts in promoting untying aid might be dampened with seemingly successful operations of emerging donors (Rowlands, 2012). In fact, the recommendation issued in 2001 has not been fully realized. Some DAC donors like Canada, Portugal, and Greece have continued to offer tied aid.

With the emergence of rising donors that overtly pursue their own interests, traditional donors began to regain some attention to commercial interests through foreign aid. Due to severe economic situations caused by the prolonged recession triggered by the Lehman Brothers crisis started in September 2008, traditional donors cannot help but take into account their economic gains through foreign aid.

The relationship between traditional donors and rising donors has become much more complex today. On the one hand, China's foreign aid norms and practices undermine some of the common efforts traditional donors seek to pursue through their ODA. On the other hand, emerging donors' aid efforts have uncovered some hidden problems and revealed some limitations of the existing aid norms and practices. The definition of ODA is a typical example. The analysis of China as a rising aid donor suggests that the measurement of development assistance based exclusively on ODA limits our understanding of international development assistance and hence needs to be reconsidered to produce better development outcomes.

In essence, China's foreign aid is not substituting for the traditional donors' ODA. They are rather complementary. Traditional donors and rising donors working in tandem can produce better outcomes of international development in this great revolutionary era for development assistance.

Chinese Literacy Acquisition: A Multidimensional Puzzle

Abstract

Literacy is a multilevel construct comprising word reading, spelling, and text reading comprehension. Understanding the key linguistic and cognitive factors that support word reading, spelling, and text reading comprehension is fundamentally important to elucidate the detailed nature of literacy acquisition. While most contemporary models of literacy acquisition are developed on the basis of English and other alphabetic writing systems, little attention has been paid to nonalphabetic writing system, such as Chinese. We focus on Chinese literacy acquisition and emphasize how different properties of the Chinese language (phonology, morphology, and orthography) may impact the development of different-level literacy skills. A systematic review of extant research on literacy acquisition, along with our own work on Chinese word reading, spelling, and reading comprehension, suggests that phonological awareness, morphological awareness, and orthographic skills are all important to Chinese literacy acquisition, but the relative importance of these skills varies across word reading, spelling, and reading comprehension. Moreover, the contribution of each of these linguistic and cognitive skills to a single component of literacy skills also varies in different developmental stages. This suggests that a full model of literacy acquisition should consider the linguistic features that are characteristics of the writing system, as well as developmental context.

Literacy is multidimensional, comprising reading, spelling, reading comprehension, and higher-order writing skills (McBride-Chang et al., 2003). Literacy acquisition is a pressing challenge faced by every child. Thus, it is vital to understand the structures and cognitive processes that underlie the acquisition of each component skill in order to provide the best support for children's literacy acquisition. A long history of research suggests that the process underlying literacy acquisition is partly shaped by the properties of a given language exhibited in its writing system. In the following section, we focus on how specific features of languages influence the acquisition of different literacy skills in reading, spelling, and reading comprehension. Writing composition in Chinese is beyond the scope of discussion here given space limitations. In addition, we will mention both Mandarin Chinese and Cantonese, the most studied languages in Chinese in the literature, in various given contexts so as to have a better illustration of the properties in Chinese.

What Are the Relations of Component Literacy Skills?

There exist intrinsic and overlapping interrelationships among the skills or recognition and spelling of characters and words and reading comprehension. Word reading is a skill of mapping a print unit onto a speech sound unit carrying meaning (Mason et al., 1991). In the early stage of literacy development, many of the processes involved in word reading are sound–sight repetition (McBride-Chang et al., 2003). When children's reading ability becomes more sophisticated, they will rely on explicit knowledge of the morphological system and orthographic system in Chinese (Perfetti et al., 2005). The skills acquired from reading lay the foundation for spelling. Spelling is an encoding process to retrieve or reproduce the print code of the spoken unit (e.g., Perfetti, 1997). It is an integrated process that requires basic skills of orthographic processing, phonological skills, and morphemic analysis; these signify the fundamental principles of a given writing system and its distinctive characteristics relating to phonology, morphology, and orthography (Perfetti, 1997). It is not surprising to find that word reading and spelling are highly associated as the linguistic factors involved in these two literacy skills overlap. While the former requires one to reproduce the print via the spoken channel, the latter is a representation of the spoken unit using print. Nonetheless, in some writing systems, the cognitive skills required for spelling may be more in-depth than for word reading. For example, in Chinese, spelling requires not only the mapping of the sound unit and the print unit, but the precise understanding of the internal structures of a character in order to produce a correct spelling of a word. Findings from a longitudinal study by Tong et al. (2011) investigating the relationship of various reading-related cognitive tasks and Chinese word reading and spelling among kindergartners affirmed the idea that although there were overlapping cognitive processes in these two aspects of literacy, there were some distinctions between them. In this study, homophone awareness, visual skills, and syllable awareness were strongly associated with word reading, but these cognitive abilities were not related to children's spelling in their early stage of literacy development.

Word reading and spelling are fundamental for growth in reading comprehension (Stanovich, 1986). Reading comprehension requires multiple cognitive and metacognitive processing such as working memory, inference, reasoning, and thinking (Crowder and Wagner, 1992). Word reading and reading comprehension are highly intercorrelated, and word reading is highly predictive of children's reading comprehension (e.g., Cunningham and Stanovich, 1997; Yeung et al., 2012; Yin et al., 2007). According to Stanovich (1986), early competence with reading skill is a good predictor of later reading proficiency. Thus, children's good word decoding skills may help them to become good readers later on.

Furthermore, word reading is recognized as the most fundamental skill to facilitate children's self-achieved information from the word (Sticht and James, 1984). The process of recognizing a word reflects the initial understanding of the correspondence between the speech sound unit and the single writing unit, while spelling shares the same processing mechanisms with word reading (Ehri, 1997). It can strengthen the sound–symbol linkage and then enhance children's understanding of the sound system of a given language and of reading skills (e.g., Ehri, 1997).

However, given that the goal of reading is to derive meaning from print, reading comprehension is the end goal of literacy (Snow et al., 1998). Not surprisingly, there is an imperfect connection between early competence in reading skill and reading performance later on (e.g., Gough and Tunmer, 1986). There is accumulated evidence that word reading, spelling, and reading comprehension are correlated, but their correlations are not perfect, indicating that they are connected, but also dissociable. The processes and outcomes of these three core constructs of literacy might be influenced by other constructs relating to linguistic forms and characteristics, as well as the developmental level of children. Here, we focus on Chinese literacy acquisition and specify how different sound and meaning structures of Chinese influence the process of Chinese literacy acquisition. We focus first on phonology, the sound system of Chinese, then on morphology, the meaning system, and finally on orthographic processing of Chinese print itself, in turn, below.

Chinese Phonology: Syllable and Tones

Chinese has a relatively simple syllable structure, consisting exclusively of syllables that are composed of V (vowel) only, as in /o1/阿 (fawn on), CV (consonant-vowel) only, as in /ma1/媽 (mother), CVC (consonant-vowel-consonant) only, as in /shan1/山 (mountain), or VC (vowel-consonant) only, as in /an4/暗 (dark), and CVVC /liang4/亮 (lightening); there are no consonant clusters, as commonly observed in alphabetical languages such as English. The examples used here are Mandarin Chinese as it is most often discussed in research and it represents one general picture of syllable structure in Chinese. CV is the most common structure in Mandarin Chinese. Although Cantonese has similar syllable structures, it is a little bit more complicated than Mandarin Chinese. For example, Cantonese allows more consonants at the end of the syllable. Despite the differences between Mandarin Chinese and Cantonese, syllabic awareness is particularly important for reading aloud in Chinese.

Also, Chinese is a tonal language. In Chinese, the change of pitch of a spoken syllable can result in changes of meanings. When talking about tones in Chinese, it is particularly interesting to use Cantonese as an example. Among Chinese languages/dialects, Cantonese has a rather complicated tonal structure that consists of at least six tones, i.e., high-level (55), high-rising (25), mid-level (33), low-falling (21), low-rising (23), and low-level (22) (Chao, 1947). For example, a single spoken syllable /fu/ can represent six different meanings of /fu55/膚 (skin), /fu25/虎 (tiger), /fu33/褲 (trousers), /fu21/符 (symbol), /fu23/婦 (woman), /fu22/父 (father) when pronouncing it with six different tones in Cantonese. Moreover, unlike other prosodic features such as intonation and stress in English, tone is fixed for a given syllable and it does not vary much across contexts (the sandhi rule, in which tones of words are influenced by adjacent words or syllables, is an exception). The ability to distinguish tone is crucial in order to have a precise understanding of the meaning of words and to be able to pronounce words correctly. There is evidence that a deficit in perceiving tone is associated with difficulties in learning to read aloud (Tong et al., 2013) and to comprehend the meaning of words (Tong et al., submitted).

Chinese Morphology: Homophone and Lexical Compounding

Chinese has a distinctive morphology in that, for the most part, each character is a morpheme, or (smallest) meaning unit. In Chinese, one morpheme maps onto one syllable. However, the number of spoken syllables is far less than the number of morphemes. For example, the number of spoken syllables used in Mandarin is about 1200, whereas regular words consist of over 7000 syllables (Li et al., 2002). Cantonese includes only 753 syllables excluding tone (Leung et al., 2004). That results in a large number of homophones, so that different morphemes (or characters) are pronounced using the same sound. For instance, one monosyllable /*lann4*/ can represent more than five characters 蘭 (orchid), 欄 (column), 瀾 (wave), 攔 (obstruct), 闌 (waning), 斕 (colorful) with different meanings in Cantonese. Therefore, without contextual cues, it is very challenging to identify the meaning when hearing a single syllable. However, by pairing the syllable with another appropriate character, for example, 專欄/zyun1 lann4/ (special column), one is able to derive the meaning from its spoken form.

Lexical compounding is the most frequently used word formation process in Chinese (Packard, 2000). In Chinese, one single morpheme can combine with other morphemes to form a new word. For example, the single morpheme 書 (*book*) can combine with other morphemes in forming into a group of compounds including 書包 (book bag), 書架 (bookshelf), and 書桌 (reading desk).

However, it is worth mentioning that the definition of morpheme in Chinese can be explained at two separate levels. One level was previously mentioned, i.e., that a single character is usually also a morpheme. For example, a single Chinese character 好/hou2/ can indicate a variety of meanings such as (1) with much merit, (2) good, the opposite of bad, (3) good relationship, and (4) accomplishment. A second level lies at the level of a structural relationship within the internal components of a character: A semantic radical offers a semantic marker. For example, 犭 and 忄 contain partial information, the former indicating canine and the latter indicating emotions or feelings. However, semantic radicals provide only rough semantic categorization of a group of characters, rather than giving exact meaning information for a given character. Therefore, it is relatively difficult to understand whether a partial meaning unit, such as a semantic radical, can be a morpheme or not given the current definition of morpheme. Also, semantic radical is part of print unit and it is operationally

challenging to measure it without involving orthographic information.

As is clear from the above description, it remains open how we could adequately conceptualize morphology and morphological awareness. In general, the morpheme could not be simply defined as a single word form. Here, we conceptualize of morpheme as an independent representation of a linguistic unit which has its own sound, meaning, and orthography, such as 車 (vehicle). Each morpheme can contain either meaning or structural features. In particular, each morpheme must have a specific meaning which is different from its unpronounceable radical. As to structure, it involves the word form and sound variation and modes for forming compound words.

Chinese Orthography: Strokes, Radicals, and Characters

Chinese has a relatively complex orthographic structure. Unlike alphabetical letters, Chinese characters are formed using strokes, which are the basic and smallest units of a character. The number of strokes of a character, on average, varies from 1 to 23. A character can be formed by as few as one stroke, such as 一 (one), or it can be formed from many strokes, which in turn comprise different radicals, such as 唱 (sing). The structure of the latter is most commonly found in Chinese characters; about 90% of Chinese characters comprise of two radicals, including a semantic radical and a phonetic radical (Ho et al., 2003). Positional regularity is found in Chinese characters. The semantic radical is usually positioned on the left while the phonetic radical falls on the right. To illustrate, a Chinese character, 泳/yong3/, which means swim, comprises a left-hand side semantic radical 氵 indicating a water-related concept and a right-hand side phonetic radical 永 pronounced as /yong3/. This regularity has been described as part of the 'orthography–phonology correspondence rules' (Ho and Bryant, 1997).

However, the links between the sound, meaning, and form in Chinese are much less systematic in comparison to English and other alphabetic languages. The associations of sound, meaning, and forms are somewhat arbitrary (Zhou and Marslen-Wilson, 1999). Around 15% of characters are irregular characters, the sounds of which differ from their phonetic radicals (Shu et al., 2003). Examples include 初/co1/ (first) (primary character) versus 刀/dou1/ (phonetic radical), 錯/co3/ (mistake) versus 昔/sik1/ (the past), 台/toi4/ (stage) versus 始/ci2/ (start); for all of these, the phonetic cues are not valid for naming these characters. It commonly occurs in Chinese writing systems that the similar visual-configuration or graphic represent very different meanings or sounds. For example, the single Chinese characters 土/tou2/ (soil), 士/si6/ (soldier), 工/gung1/ (worker) are composed of the same number of identical strokes, but the sounds and meanings are markedly different. On the other hand, no systematic grapheme–phoneme correspondence makes the separation of phonological awareness and orthographic measure feasible in Chinese. These typical features relevant to Chinese orthography may suggest that Chinese children need to rely on visual distinction or memorization of visual-orthographic patterns to correctly identify Chinese characters.

Literacy Acquisition: Phonology, Morphology, and Orthography

Reading and writing are the most important literacy skills learned by young children and they are likely to be intrinsically linked with metalinguistic knowledge (Nagy and Anderson, 1999). Several models of early reading have established the connections among these metalinguistic skills across languages (e.g., Perfetti et al., 2005; Seidenberg and McClelland, 1989). A single mechanism model based on English word reading has conceptualized that phonology, morphology or semantics, and orthography are three interlinked constituents of word recognition. Moreover, the representation of each constituent is influenced by the levels of the other constituents (Plaut et al., 1996; Seidenberg and McClelland, 1989). Extending one single mechanism model to Chinese word reading, the lexical constituency model also recognizes that word identity is constrained by phonology, semantics, and orthography. The process of identifying the word involves a multifacet activation of these three constituents. The sound information is simultaneously activated along with the process of retrieving the meaning from a visual-orthographic unit (Perfetti, Liu, and Tai, 2005). In addition, one recent study used a triangle model to simulate Chinese word reading and found that results were quite different from English in that the processing route from orthography to semantic was much faster than the mapping from orthography to phonology, whereas it was the reverse in English (Yang, Shu and McCandliss, 2013).

Across computational models of word reading, phonology, semantics, and orthography are consistently viewed as three core constructs of word reading (Perfetti et al., 2005). Of these three components, phonology is viewed as the sound system relating to a given language. Phonological awareness is the counterpart construct to measure children's sensitivity or awareness of the sound structure of language in reading study. Semantics can be understood as meaning of the words and sentences in terms of a linguistic framework. Morphology is focused on the study of morphemes. Given this, morphology and semantics are inextricably linked and mutually represented at the word level. Particularly, morphological awareness is most often used to assess semantic knowledge or structure in the reading realm. In addition, orthographic processing refers to understanding a set of conventional or legitimate rules in structuring the written unit. As a logographic system, Chinese has no phoneme–grapheme correspondence. However, there exist some prespecified rules in constraining unpronounceable strokes or components in forming a meaningful square-shaped character.

That is, there are a number of rules codified in the Chinese writing system, defining the specific order of strokes in forming proper Chinese characters. There are six basic types of stroke rules, namely horizontal before vertical, left diagonal before right diagonal, top before bottom, left before right, outside before inside, and inside internal stroke before the outside-sealing stroke. Therefore, sensitivity to the graphic structure and sequence of laying out the strokes might be helpful to correctly identify or retrieve the character to some extent. The potential functions of strokes in Chinese have been documented in a few studies. In a priming study, Flores d'Arcais (1994) found that stroke sequence could serve

as a lexical retrieval from memory in reading Chinese characters. Stroke sequence itself will likely activate one's orthographic presentation from the memory; hence, it is easier to retrieve related characters.

As mentioned, computational models of word reading underscore the importance of phonology (Perfetti et al., 2005). To assess children's knowledge of phonology in their given knowledge, we test their phonological awareness. Phonological awareness is a single and unified ability to recognize, discriminate, and manipulate the sounds in one's language and it manifests itself in different skills through preschool and the early elementary school years (Adams, 1990). Moreover, phonological awareness is bidirectionally associated with reading and writing (Perfetti et al., 1987) and it is the most reliable metalinguistic prerequisite for reading in an alphabetic writing system, primarily because reading and writing can strengthen children's phonological awareness development via this interactively reinforced process (Bialystok et al., 2005a; Bialystok et al., 2005b; for a review, see Adams, 1990). Phonological awareness is a strong predictor of children's progress in learning to read in Chinese (Bialystok et al., 2005b; McBride-Chang et al., 2004).

However, the relative importance of phonological awareness for reading and writing may vary across languages. For example, the prediction power of syllable awareness is robust in Chinese while phonemic awareness is predominant in English (McBride-Chang et al., 2004). Moreover, phonological awareness may be language-specific and its primacy level depends on the accessibility of phonological units in a given language system, while reading skills are developed separately and are determined by language proficiency and instruction (Bialystok et al., 2005b). For example, one study that compared the performance of phonological awareness and reading skill among English–Cantonese bilinguals, Cantonese–English bilinguals, and monolingual English speakers demonstrated that the two bilingual groups performed equally well in syllabic awareness, because the syllable is the most salient unit in Chinese. In contrast, both groups of Canadian children outperformed Hong Kong Cantonese–English bilinguals on phoneme-onset deletion phoneme counting tasks (Bialystok et al., 2005b), at least in part because phoneme skills are not emphasized in work with Hong Kong Chinese children. A 2-year longitudinal study (Tong et al., 2011) also showed that syllable awareness uniquely contributed to Chinese word reading and spelling among kindergarteners across time after all other contributions such as age, vocabulary knowledge, and nonverbal IQ were statistically controlled.

There were several other studies (e.g., Chow et al., 2005; McBride-Chang et al., 2004) that also found that syllable awareness was a strong predictor of reading ability among young children in Chinese. However, it is noteworthy that the importance of phonological awareness may diminish with age. As shown in the study by Tong et al. (2011), the contribution of syllable awareness to word reading decreases with age. Most likely, strategies or processes involved in word reading change as one's reading abilities get more sophisticated. Perhaps it is because of the unique writing system in Chinese that phonological structure is not as salient as it is in alphabetic languages. The reader may need to rely on other cognitive skills such as morphological awareness and orthographic awareness to further assess the meaning of words in Chinese. Homophones were a consistently unique predictor for word reading across time in that study. As mentioned previously, homophones constitute a salient feature in the Chinese language system and hence children's sensitivity toward homophones may explain their ability in mapping a single syllable to different meanings and different print configurations, facilitating their abilities in word reading.

Tone awareness is another crucial element in Chinese phonology. As suggested by several studies (e.g., McBride-Chang et al. (2008); So and Sigel, 1997; Yeung et al., 2012), tone detection ability is highly associated with children's reading skills. A study conducted by So and Siegel (1997) to examine the relationship between Chinese reading ability and tone awareness among primary school children showed that the development of tone awareness may facilitate word decoding skills. The study showed that children in the poor reading group particularly have problems in mapping printed characters with sounds as well as in understanding the meanings of characters. That suggests an interaction between phonology and semantics within the orthography in Chinese. The study suggested that the ability to manipulate the tones system in order to pronounce words correctly and to distinguish different homophones with variations in tone may be highly associated with children's word reading (e.g., Leong, 1996). Therefore, it is reasonable to assume that homophones and tone awareness, two salient features in the Chinese phonological system, are important in understanding children's reading acquisition. However, the importance of these cognitive processes varies with children's age, and that fact may explain why the decoding processes involved in word reading change when children's reading becomes more sophisticated.

According to Ku and Anderson (2006), learning to read is not only a task of decoding the orthographic unit, i.e., converting it to a phonological unit, but also of mapping the sound to the meaning unit (morpheme). Morphological awareness is viewed as the ability to be aware of and manipulate the morpheme, employing rules of word formation. In the intervention training conducted by Zhou and Marslen-Wilson, 1999, after a 2-month training on lexical compounding, a good indicator or morphological awareness in Chinese, children's word reading had improved significantly. An emerging consensus in reading is that morphological awareness is one important construct to understand reading acquisition beyond phonological awareness across orthographies (Carlisle, 2000; Li et al., 2002; Packard, 2000). Inflections, derivations, and lexical compounding are the most often tested in alphabetic languages (Anderson, 2003; Casalis and Louis-Alexandre, 2000; Lewis and Windsor, 1996; Nagy et al., 2006). Moreover, children's acquisition of inflectional knowledge comes earlier than derivational and compound knowledge. However, inflectional morphology is not a particularly important or strong feature of Chinese. In contrast, compounding morphology is predominant in Chinese because a great number of Chinese words are compound words. Moreover, children's ability to flexibly manipulate the morpheme might facilitate the process of mapping a speech unit onto a Chinese character (McBride-Chang et al., 2003). However, the extent to which morphological awareness contributes to different components of reading (e.g., single-morpheme and multiple-morpheme word reading and text reading

comprehension) may vary because the demands for meaning information necessary for single-morpheme reading, multiple-morpheme reading, and text reading comprehension differ. This is an unresolved issue that needs further research.

In the previous paragraphs, we mentioned the relationship of morphology and orthography. Orthography plays a particularly important role in Chinese due to its complex visual structures. Orthographic awareness is sensitivity to orthographic regularities (units of print) in the language. There is substantial evidence showing that orthographic knowledge affects Chinese children's performance in word reading (e.g., Ho et al., 2003; Lin et al., 2010; Packard et al., 2006). The association of orthographic knowledge and children's word reading was shown by Ho et al. (2003) in their study of pseudocharacter reading tasks in Hong Kong Chinese kindergartners, first-graders, and third-graders. Children's use of radical knowledge in relation to position and function regularity increases as children's reading competency grows. These findings offer evidence that orthographic knowledge of stroke patterns and positional constraints of radicals play an important part in Chinese word reading, and they lend credence to the hypothesis that understanding the positional regularity of functional components of the Chinese orthography may contribute to Chinese word reading. Also, a mother–child joint study conducted by Lin et al. (2010) reported that by implementing analytical strategies such as the orthographic strategy of teaching kindergarten children functions of semantic and phonetic radicals, children showed better performance in their word reading skills. Additionally, they found that orthographic awareness uniquely explained character reading.

Orthographic processing is viewed as a construct that is entangled with phonological awareness in English word reading (Foorman, 1994) and some evidence from previous studies has suggested that orthographic processing and phonological awareness are reciprocally influenced in reading and spelling across languages (e.g., Foorman, 1994). The route and the magnitude of the contribution of orthographic processing to word reading might vary across languages. One study from Huang and Hanley (1995) compared word reading among children from England, Taiwan, and Hong Kong. In that study, visual paired associates learning skills, involving memorization and linking of color to abstract figures, was uniquely associated with word reading ability in Taiwan and Hong Kong even with IQ and vocabulary skills partialled, but not among British children. Also, visual-orthographic measures contributed substantially to early Chinese word reading whereas phonological awareness predicted later Chinese reading (Ho and Bryant, 1997b). In addition, Siok and Fletcher (2001) adopted diverse levels of visual-orthographic and phonological awareness measures and suggested that learning to read Chinese develops from a logographic to an orthographic-phonological stage (Siok and Fletcher, 2001).

Although the existing literature is mainly focused on the linkage between metalinguistic skills and word reading, there are also several studies that have moved beyond word reading to other literacy skills, such as spelling and reading comprehension. As described before, spelling and word reading are different sides of the same process (Ehri, 1997). Spelling is the process of employing multiple metalinguistic skills, as well as orthographic knowledge, across developmental stages (Ellis, 1998). Moreover, spelling requires the integration of metalinguistic skills related to speech with orthographic knowledge about print (Leong, 1999; Treiman, 1993). Of these, orthographic knowledge is initially used in reading and is further transferred to spelling (Firth, 1985). Also, morphological awareness and orthographic processes influence early spelling (Bryant, Nunes, and Bindman, 1999; Goswami, 1999). There exists evidence suggesting that phonological awareness, morphological awareness, and orthographic processing are all effective predictors of spelling, but the extent to which each linguistic or cognitive skill is important for spelling varies by language and task (Walker and Hauerwas, 2006). For example, Tong et al. (2011) found that syllable awareness and orthographic skills contributed to kindergarteners' word spelling. However, this effect was eliminated once word wording was statistically controlled. A theoretical reading model proposed by Yeung et al. (2012) showed that morphological awareness uniquely explained first-graders' word reading and spelling when other cognitive constructs such as phonological skills, orthographic skills, and rapid naming were statistically controlled. In this model, both orthographic skills and morphological skills are individually important for literacy development in Chinese.

In contrast, there have been few studies on the association between metalinguistic or cognitive constructs and reading comprehension among young children. Reading comprehension is a higher-order reading skill which requires the reader to construct meaning from print. Morphological awareness is crucial to the development of reading comprehension. A growing number of studies suggest that children's performance on morphological awareness tasks are predictive to the growth of reading comprehension even when controlling critical reading-related measures, such as phonological awareness and vocabulary (e.g., Deacon and Kirby, 2004; Kirby et al., 2012; Carlisle, 1995; Kieffer and Lesaux, 2012).

Over the last two decades, research on Chinese literacy acquisition has made significant progress in identifying factors that affect literacy acquisition. Different aspects of literacy skills overlap with each other but meanwhile each of these skills has its distinctive elements. However, how these factors interact in the process of literacy development, and jointly contribute to the growth of literacy skills, remains unclear. New research is needed to solve the multifaceted puzzle. In addition, there are few studies on Chinese reading comprehension, so future work may probe further into the relationship between reading comprehension and other cognitive constructs, as well as the relationship between reading comprehension and other literacy skills. These are important in understanding writing and reading acquisition and may help to solve the multifaceted puzzle of Chinese literacy.

Chinese Revolutions: Twentieth Century

Abstract

China was once seen as having a population that was unusually prone to 'rebellion' but not susceptible to 'revolutions,' that is, upheavals capable of doing more than just changing who was on the throne. The twentieth century, however, saw a series of interconnected revolutions (e.g., one associated with the name Sun Yat-sen and others with Mao Zedong), which between them thoroughly transformed the country. These events fit in well with some standard ideas about revolution promulgated by social theorists primarily interested in and most knowledgeable about the Western and Russian examples, but in other regards call them into question.

The Chinese were once thought to be the least revolutionary of people, yet the period beginning in 1911 was one in which China was altered forever by a series of revolutionary struggles. These struggles need to be understood as both divisible (in that they broke out at different times over the past century and often affected only certain aspects of the social and cultural order) and parts of a single whole (since many Chinese political actors conceived of themselves as participating in a unified Revolution, the goal of which was to radically transform the country's internal working and its place in the world). The tension between thinking in terms of multiple lower-case 'revolutions' and a singular upper-case 'Revolution' is, in China's case, crucial to keep in mind and impossible to resolve without doing a disservice to the country's complicated twentieth-century history. The Chinese experience confirmed some conventional social scientific ideas about revolutions generated from the study of European cases (e.g., the idea that ineffective reforms often pave the way for revolutions), while calling into question others (e.g., the notion that villagers could never be key players in radical movements for change).

In the 1800s, a leading sinologist claimed that the Chinese were the 'most rebellious' but 'least revolutionary' of peoples and Karl Marx, along with other Western social theorists, argued that peasants would never be the driving force in radical movements for change (Meadows, 1856, p. 25; Feuer, 1959, pp. 319, 338). The twentieth century would prove both the sinologist and the theorists wrong – many times over. Nearly every decade of it saw a revolutionary event of one kind or another break out in China. In many of these, residents of the Chinese countryside, where until recently a great majority of the nation's population lived, played central roles.

Key Events

The first quarter of the twentieth century witnessed a series of interrelated insurrections that toppled the Qing Dynasty (1644–1911). Known collectively as the 1911 Revolution, these upheavals paved the way for the establishment of the Republic of China (ROC) on 1 January 1912, which was also when a revolutionary activist, Sun Yat-sen (1866–1925), became this new country's first President. A pathbreaking student-led mass struggle also took place in the century's first quarter. This was the May Fourth Movement of 1919, which began with a rowdy student demonstration in Beijing protesting the terms of the Treaty of Versailles that would cede to Japan parts of China previously under German control. The struggle gained momentum and support from other classes after police arrested some of the Beijing students and ended with the dismissal from office of three high-ranking officials who educated youths claimed were insufficiently patriotic. In addition, the period saw two revolutionary organizations formed: the Nationalist Party or Guomingdang (GMD), which was led initially by Sun and then after his death by Chiang Kai-shek (1887–1975); and the Chinese Communist Party (CCP) whose most important leaders have been Mao Zedong (1893–1976) and Deng Xiaoping (1904–97).

The second quarter of the century began with the GMD and CCP working together in a United Front (1924–27) orchestrated by Sun and his Soviet advisor Borodin. The alliance's goal was to defeat warlordism and imperialism and thus get the *Geming* (a Chinese term for revolution whose shades of meaning are discussed below) back on track. In 1927, however, Chiang turned on his erstwhile allies, who had just helped him reunify the country through the military campaigns and mass movements known as the Northern Expedition. He launched a White Terror against members of the CCP and left-wing rivals within the GMD. After 7 years, after persistent and bloody but never quite conclusive GMD extermination campaigns, most of the remaining members of the CCP, including both Mao and Deng, set out on their epic Long March (1934–35) to safety in isolated northern base areas. The two organizations, each tightly disciplined and Leninist in structure, allied again from 1937 to 1945 in a Second United Front against Japan. The 1925–50 period concluded, however, with a Civil War (1945–49). This ended with the GMD's retreat to Taiwan and Mao's proclamation, on 1 October 1949, of the establishment of a new People's Republic of China (PRC) – something that this son of a relatively well-to-do farmer was only able to do because his party had won so much support in China's countryside. The CCP then launched a series of radical initiatives, including a partially successful effort to gain adherence to a new Marriage Law (1950) that gave women equal rights in family matters and strove to minimize the power of patriarchal kin groups.

The century's third quarter began with Mao taking the lead in further campaigns, all of which were carried out in the name of The Revolution and some of which caused enormous misery. One of most notorious was the 'Anti-Rightist Campaign' (a Red Terror directed largely against intellectuals). The most consequential and disturbing was the 'Great Leap Forward' (a bizarre experiment in irrational utopianism that contributed to a famine of horrendous proportions, causing the deaths of tens of millions of people). Later in this quarter century, Mao, angered by his post-Great Leap marginalization within the CCP hierarchy, rallied young loyalists (Red Guards) to challenge the Party bureaucracy. Thus began the Cultural Revolution (1966–76). Mao's charge, soon echoed by the Gang of Four (a clique that included Jiang Qing, his wife), was that high officials had lost their revolutionary zeal and become corrupt. A revolution within the revolution was needed, they argued, to get the sacred *Geming* back on course.

The Cultural Revolution spiraled into a chaotic war of all against all that continued into the first year of the century's final quarter. This period also witnessed the abortive revolution of 1989, during which giant demonstrations took place in Beijing and scores of other cities. In the ROC (as Taiwan was rebaptized in 1949), a major breakthrough came with the lifting of a decades-old policy of martial law. This laid the groundwork for an East Asian variation of the 'Velvet Revolutions' and 'Handshake Transitions' of Central Europe: the nonviolent transfer of power from the GMD to an opposition party early in the year 2000.

By the end of the 1900s, so many aspects of Chinese politics and society had been transformed or challenged by insurgents that it now seems strange that the first edition of this Encyclopedia included an article on 'The Chinese Problem' but not 'The Chinese Revolution.' The rise of the CCP and the Cultural Revolution still lay in the future when that entry was written, but there were clear signs by then that the twentieth century would be viewed as a revolutionary one for China. One indication of just how revolutionary is that, by the 1990s, many Chinese were living lives that would have been unrecognizable to their great grandparents or even their parents. Moreover, the words 'China' and 'revolution' were by then inextricably linked in the minds of many people. A newly created and little known compound term early in the 1900s (one of the first important tracts to use it appeared in 1903), by the middle part of the century, it was one of the most important keywords of Chinese politics, with figures on both the right and the left denigrating the other as 'counterrevolutionaries,' who had abandoned the cause of the Geming. Its centrality only began to lessen in the 1990s and first years of the twenty-first century, as a focus on economic growth and national strength took priority, but even now it exerts a special force.

The linkage between 'China' and 'revolution' was particularly strong in the first decades of the PRC's existence. Under Mao and even under Deng, who took control in the late 1970s, the term *Geming* was invested with a holy patriotic meaning. And in the wake of the 1989 protests, which were suppressed with brutal force and triggered an ongoing legitimacy crisis, the authorities found it useful to play the revolutionary legacy card, insisting, for example, that the protesters who took to the streets in 1989 had created 'turmoil' that threatened the Revolution. Finally, in 1997, the government moved to ratchet down the potency of the term by claiming that henceforth writing 'counterrevolutionary' tracts or taking 'counterrevolutionary' actions would no longer be considered crimes – instead things previously classified as 'counterrevolutionary' would be denigrated by other words, such as 'subversive,' for example. This adjustment of the legal code, though, did not mean the end of all efforts to play the rhetorical card of *Geming*. In 1999, for example, when American bombs mistakenly killed three Chinese citizens working in the country's Belgrade Embassy, the victims were quickly dubbed 'revolutionary martyrs' and the official media linked these new deaths to those of patriotic participants in hallowed historic events of the 1910s–50s.

In addition, even though Westerners often view the words 'reform' and 'revolution' as contrastive, in China *gaige* (reform) was often presented by Deng, and has sometimes been presented by his successors, as a method for carrying forward the *Geming*. The policy of opening the PRC to international trade and moving away from a command economy that Deng and after him Jiang Zemin (1926–till date) and Hu Jintao (1942–till date) have followed since 1979 is typically presented in English language works as a pragmatic 'Reform Program' and a step away from state socialism. Its PRC proponents, however, describe it as an effort to 'build socialism with Chinese characteristics' and an effort to keep the Revolution from ossifying.

It is not just in the PRC that the words 'China' and 'revolution' have often gone together naturally. Most of the few Chinese names and faces recognized by foreigners are those of insurgents – from Mao to the anonymous Tank Man of 1989. And many ROC residents grew up learning history from schoolbooks that treated the story of the 1900s as an unending revolutionary struggle, which encountered a terrible setback in 1949 but did not die.

Categories and Definitions

This brings us to a question too rarely addressed: did China experience one Revolution or several? Many official PRC histories (as well as some Marxist ones in other languages and standard GMD accounts) refer to a single ongoing Revolution with many stages. Western social theorists (such as Theda Skocpol) and comparative historians (such as Crane Brinton) sometimes prefer to think of a single great event that began in 1911 and ended in 1949. They then fit this almost 40-year-long event into a Great Social Revolution model that is also used to interpret more compact phenomena such as the French upheavals of 1789–99. Many non-Marxist sinologists, meanwhile, speak of three relatively discrete revolutions: a Republican one in 1911, a National one in the 1920s, and a Communist one.

The Term '*Geming*'

Complicating these questions is the term *Geming*, the meaning of which at times overlaps with, and at others diverges from, its Western equivalents. *Geming* literally means 'stripping the mandate,' that is, the successful carrying out of an upheaval that demonstrates, through its ability to overturn a ruling house and establish a new dynasty, that heaven now sides with

a new regime. It was only from the 1890s on, in part because of new senses the characters had acquired in Japan, that *Geming* began to be linked to the creation of a new political system, not just completion of a dynastic cycle. *Geming*'s original linkage to dynastic cycles makes it curiously like its English and French counterparts, in which visions of return and of forward movement alike can be found. In 1789, the Janus-faced aspect of revolution was signaled by the use of classical goddesses to portray new political virtues. In the 1910s, it was signaled by anti-Qing leaders alternating between presenting themselves as avenging the legacy of the Ming (1368–1644), the ethnically Chinese ruling group the Manchus had displaced, and as struggling to create a new system.

If there are overlaps between the terms 'revolution' and *Geming*, however, there is also a difference: it is never clear whether the sense of the Chinese word is singular or plural, lower or upper case and whether a text is referring to The Revolution or one of many. This is more than merely a linguistic issue: to compare events, we need to know when they began and ended. With France, for example, there is a consensus that the revolution began in 1789 and lasted about a decade, although other supplemental revolutions occurred later (1830, 1848, and 1871). With China, there are more options, including the three alluded to above.

Problems with Standard Categorization Schemes

There are, however, limitations to each. The continuous Revolution vision focuses too tightly on the achievements of a particular organization. It distorts the shape of twentieth-century history by downplaying struggles not guided by the particular Leninist party – the CCP or the GMD.

The 1911–49 vision is problematic for use in comparison, even though comparativists champion it. Skocpol, for example, does not explain why, if the 'Great Social Revolutions' are essentially alike in structural terms, the Chinese one took so much longer to play out. Brinton's 'anatomy of revolution' model becomes problematic because 'terrors' occurred at different points in the Chinese *Geming*. In other revolutions, he claims, this 'fever' hit the patient just once, then broke.

A tripartite schema, finally, leaves too little room for radical developments that do not move in lockstep with the rise of governments; 1911, the late 1920s, and 1949 were key turning points in the political story but not necessarily in the social and cultural ones.

Overlapping Revolutions

A more satisfying approach divides China's recent past, for heuristic purposes, into four overlapping revolutions, each following its own timetable: one political, one cultural/intellectual, one diplomatic, and one socioeconomic. Let us consider each briefly.

Politics

The political revolution has the clearest starting date: 10 October 1911. GMD official historians present the events that followed the Wuchang Uprising of that day (really a military mutiny) as adhering to a master plan crafted by Sun Yat-sen and carried out by members of his Revolutionary Alliance, the organization that evolved into the Nationalist Party. But many participants had no contact with the Alliance and knew little of Sun or his ideas. Only some were committed to republican ideals. Others were motivated by distrust of the Qing 'barbarians,' anger at particular officials, or a desire to be on the winning side of a Mandate shift.

Still, the 1911 Revolution extinguished not just a dynasty but a system; hence it deserves to be thought of as politically revolutionary. The National Assembly and other republican institutions quickly proved ineffectual. But the complete failure of attempts by Yuan and later another warlord to found new dynasties demonstrated that the rules of political life had changed.

Cultural and Intellectual Change

Attempts by Chinese revolutionaries to transform traditional belief structures and patterns of behavior began after the Opium War (1839–42). The military defeat suffered then by China led some within the dominant scholar–official class to begin questioning longstanding assumptions about the inferiority of foreign cultures. The first generations of intellectuals to rethink these issues, while interested in specific things the West had to offer (*yong* or techniques), were seldom revolutionary in their approach to questions of fundamentals (*ti* or essences). Their belief in the superiority of traditional moral codes remained unshaken; they merely sought efficacious ways to combine Confucian *ti* with Western gunboats and other sorts of foreign *yong*.

The *ti/yong* distinction remained at the heart of the debate for decades, until the iconoclastic New Culture Movement (1915–23) led by intellectuals who had gone abroad, usually to Japan, or been exposed to foreign ideas at one of China's recently formed Western-style schools. They disagreed about many things but shared three convictions. China's weakness was due to the enduring power of entrenched 'Confucian' and 'feudal' beliefs (such as the veneration of age) and practices (such as arranged marriages). The Chinese should welcome the best the West had to offer: ideas and methods of inquiry included. And intellectuals needed to educate and mobilize others.

Much New Culture Movement energy was directed toward the publication of new periodicals, which were filled with articles introducing and often lauding Social Darwinism, Pragmatism, Anarchism, Marxism, and other imported ideologies. These periodicals also attempted to serve another purpose: their articles, written in a 'plain speech' as opposed to a 'classical' style, were supposed to inform and inspire the masses. This literary move to break down the barriers between intellectuals and nonintellectuals was reinforced by public speaking campaigns on issues ranging from medicine to international affairs.

An important new turn came with the May Fourth Movement, when student activists with ties to the New Culture Movement actively appealed to members of other classes to join them in protesting the terms of the Treaty of Versailles and the corrupt and autocratic domestic authorities who were doing too little, they claimed, to protect the nation. After sympathy strikes by workers and merchants and a widespread boycott of Japanese goods, the students achieved their main

domestic goals: the dismissal of the three officials they hated most and the release of all those arrested for protesting. But their inability to stop the Treaty of Versailles from taking effect illustrated the need for a diplomatic revolution.

Diplomatic Change

No diplomatic revolution could take place until the rise of a strong central government committed to overturning the unequal treaties forced upon the Qing by foreign powers. The Northern Expedition brought this about. After reunifying the nation, however, Chiang claimed that the spread of communism was more dangerous than the continuation of imperialism. Unlike some of his warlord predecessors, Chiang was an outspoken critic of the unequal treaties, but he insisted that China could only regain its place in the world once its house was in order.

World War II precipitated a sea change, as China's position as one of the *allies* gave its leader new leverage in pushing for an end to unequal relations with the West. And, in 1943, the allies renounced all claims to special privileges within Shanghai and other 'treaty port' cities. This decision and Japan's withdrawal in 1945 made China freer of foreign influence than it had been for a century.

CCP historians argue, however, that the diplomatic revolution was still not complete – and they have a point. The GMD regime remained economically and diplomatically dependent on the United States. If credit for starting the diplomatic revolution rightly goes to Chiang, it remains true that China did not fully regain its status as an independent country until after 1949.

Socioeconomic Change

The socioeconomic revolution also began long before the Communists came to power. Most notably, the late Qing and Republican (1912–49) eras saw dramatic shifts in the types of people in control of the government and witnessed the rise within the social hierarchy of merchants. But the development of new alignments near the top, although important, did not have much effect on the lives of the vast majority of Chinese who continued to reside in villages and work in small plots of land. For them, a socioeconomic revolution did not take place until the CCP's land reform campaigns. This socioeconomic revolution (like the others) did not hit all parts of the country at the same time but rather played itself out according to regionally distinctive timetables. By the early 1950s, however, it had affected most of China's villages.

Unfinished Revolutions

If China's twentieth century is envisioned as a time of multiple revolutions, we need to keep in mind that most were incomplete – and that struggles for change in other spheres were pursued sporadically but never fully carried through. One important unfinished *Geming*, linked to but not quite the same as any of those just described, was the revolution for women. Aspects of sexual politics changed throughout the 1900s, but the dream of complete equality promoted by revolutionaries in various decades never became a reality. And forward movement toward male–female equality has sometimes been followed by a period of backsliding; in post-Mao China, women retain many of the rights they were formally accorded by the New Marriage Law of 1950, for example, but many see the recent past as one in which the status of women has declined in some spheres at least. Much the same can be said for the democratic revolution: calls for democratization were heard often during each stage of the *Geming*, but oligarchy and one-party authoritarianism have tended to prevail – and still do prevail in the Chinese mainland.

Ironically, although China's twentieth century was filled with transformations, its final two decades were strikingly similar to its first three. In Taiwan, moves to institute a system of free elections recalled experiments made around 1911. On the mainland, there were May Fourth era parallels for the calls in 1989 for an end to corruption. And in the automatic weapon fire that accompanied the massacres of June 1989 (the famous one in Beijing and a less well-known one in Chengdu), there were echoes of killings of the 1920s and the 1930s that were justified as necessary efforts to maintain order and/or protect the *Geming*.

Lessons from the Chinese Case

China's twentieth-century experience suggests the need for social scientists to pay more attention in the future to several factors. One, already mentioned, is the revolutionary potential of villagers. Another is scale. Revolutions have often been treated as purely 'national' events. Recent work on China shows that local dynamics are often crucial – even in upheavals driven by nationalism. So, too, are transnational flows of people (key participants in 1911 were overseas Chinese), ideas (each twentieth-century revolutionary outburst was inflected by a mixture of domestic and imported theories and notions), and money (funds coming in from Hong Kong, then still a British Crown Colony, for example, helped keep the 1989 protests going). This suggests that, in future, models used for comparing revolutions will need to make more room not only for revolutions of widely varying lengths but also for revolutions that were influenced by local, national, and transnational impulses and actors.

However, China's twentieth-century history reinforces some important insights into the comparative and theoretical literature on revolutions. It shows that Alexis de Tocqueville was right to insist that nothing does more to inspire revolutionary activism than an inefficient authoritarian regime's introduction of a reform program that offers too little and comes too late – an insight whose significance clearly still has twenty-first century relevance, as Arab Spring struggles have shown. The 1911 Revolution (which was preceded by unsuccessful Qing reforms) and even, in a way, the mainland's abortive revolution of 1989 and the much more recent fall of the GMD in Taiwan illustrate the power of Tocqueville's insight. These cases also illustrates the value of stressing, as Marx and Skocpol among others have, the revolutionary potential of groups at the fringe of the governing elite who have rising expectations and are frustrated by being kept away from real power – although on the mainland, in contrast to Taiwan, the Leninist Party in control has so far proved effective at co-opting a rising middle

class that might have been expected to push for movement toward democracy. In addition, Chinese events of the third quarter of the twentieth century in particular underscored the validity of the claim made by both Tocqueville and Skocpol, again among others, that revolutions, while attempting to do other things, often end up strengthening the power of central governments. Finally, the Chinese case shows just how much truth there is in the tragic maxim that revolutions all too frequently and all too regrettably end up devouring their own children.

A Twenty-First-Century Perspective

Looking back at China's twentieth-century revolutions from this point early in the second decade of the new millennium, some final comments are in order. The opening years of the twenty-first century have seen, according to the Chinese government's own estimates, tens of thousands of protests, in which citizens have called attention to abuses of power and sought redress for their grievances. In some cases (usually when the focus is a local issue and only a single social group is involved), protesters have gotten important concessions from the authorities. In other cases, the struggles have been met with harsh repression. What there has not been so far, due to various factors, is any kind of sustained and organized revolutionary movement that poses a real threat to the political status quo.

It is not enough to say that recent events prove that the Chinese people are exceptionally 'rebellious' but not naturally 'revolutionary' as that nineteenth-century bromide was proved unfounded by twentieth-century events. The explanation needs to be sought elsewhere. An exhaustion with revolutions, which proved so costly in the past century, could be a factor. Efforts by the authorities to clamp down quickly on any form of organized opposition is surely also part of the explanation, as is the way in which recent economic growth has made many Chinese from different walks of life feel, more than they did in some previous periods, that they have distinctively different sets of interests and aspirations. Still, the potential for revolutionary activism in the future (albeit perhaps the quite distant future) cannot be discounted, as many of the grievances that have fueled past risings in China and other parts of the world, such as intense disgust with nepotism and corruption and others kinds of abuses of power at the top, continue to plague the People's Republic.

Choice, Empowerment, and Social Work

Graeme Simpson, University of Wolverhampton, Wolverhampton, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Choice will be examined through five perspectives incorporating an international perspective. First, agency examines the capacity for autonomous actions, in short, self-determination. Second, choice as empowerment examines the concept of an engagement with promoting and working toward change both on a personal and political level. Third, choice as consumption explores the development of the 'citizen consumer.' Fourth, choice as policy examines the extent to which choice has become the acceptable face of neoliberal politics often masking other economic agendas. Finally, choice will be considered as 'collective action' as an antidote to the individualization inherent in much contemporary policy.

Choice

'Choice' has been a feature of social work throughout its history. Choice, within the field of social work and social policy can be understood in many ways and this article will identify five possible ways of examining and understanding 'choice' as a concept. First, choice will be explored through the concept of agency, rooted in the notion that humans have the capacity for autonomous actions, which in given situations will allow for choices to be made – in short, self-determination. This is perhaps the most obvious understanding of choice within social work; however, social work is a complex profession, which draws its underpinning rationale from many sources; so, the second long-standing idea of choice is that of social work being engaged with promoting and working toward change both on a personal and political level; in short, social work seeks a 'better world.' Recently, these strands have found a unified voice under the broad concept of empowerment. Recently, in developed welfare regimes, choice has become increasingly embedded into policy, where those people who use services are being seen as 'consumers of service.' This is particularly evident in developed liberal democracies, and this article will draw mainly (but not exclusively) upon the United Kingdom as an example of this. Thus, the fourth area is that of choice as 'policy,' which itself is closely connected with the final area of examination, which is that choice has become an acceptable face of neoliberal politics in advanced welfare societies, often masking other economic agendas – for example, the 'austerity' agenda from 2009 onward. Finally, choice will be considered as 'collective action' as an antidote to the individualization inherent in much contemporary policy.

Choice as Agency

Those who have engaged in social work have always held that those they work with have a right to self-determination. In essence, it means that social workers do not impose interventions or support upon their service-users or clients, but rather that the service-user has engaged 'voluntarily' with the social worker. Such a principle is embedded within social work's current and also historical codes of ethics and conduct. It was part of Biestek's (1961) ethical principles that stated that client self-determination should be central to all social work practice. The notion of self-determination can be traced to European philosophical traditions, notably the eighteenth-century Enlightenment. In this context, individual self-determination was founded upon the idea that people were capable of organizing their own affairs and was instrumental in challenging (if not rejecting completely) previous ideas of 'God-given' laws. In other words, people have choice (agency) to direct, control, and organize their lives and through choice, people are self-determining 'free' beings.

Even as such a view was being promoted, the French philosopher Rousseau posed a challenge in that people are "born free, and everywhere in chains" (This is a standard English translation of the original French: "L'homme est né libre, et partout il est dans les fers.") (2007/1762: p. 3). Thus, whatever free choices people may have, they are also somehow constrained by their situation. In the contemporary debates around agency, this can be put slightly differently. Social workers understand that the people they work with frequently make choices constrained by their circumstances; likewise, they, as social workers, also have their professional choices constrained. Many social workers quickly realized that as social workers, their 'choices' are limited by a range of factors beyond their control, for example, funding, procedures, and other political decisions. Social workers also understand that many of their service-users lead lives that are at least in part, influenced – if not directly determined – by external forces. This is perhaps put into even sharper focus when considering social work at a global level and the extreme financial poverty of people in the underdeveloped South. External forces, or structures, are often seen as not only limiting choice (or agency) but also making it an almost redundant concept. So, for social work, and for that matter social policy, choice becomes not something that can be taken for granted, but something to be examined and explored, often within the polarization of the agency-structure debate, where agency equates to individual choice, and structure to external forces that people experience and that will shape their lives.

This debate will be familiar to all those who engage in the delivery of any form of social welfare and a potential resolution is to suggest, following the work of Lavin (2005), that people's actions have to be understood within the context of wider social relationships and this would include arguably abstract factors such as the economic and social structures of any given society.

Within social work, and social welfare, there remains, however, a strong belief in choice – or agency, and yet most social workers would not entirely ignore the question of circumstances or environment, even though many procedural and legal directives would ultimately locate the actions with the individual and not the structure. It is arguably not so straightforward, as the well-documented example of child maltreatment highlights. Even though most cases of child maltreatment occur among people who could be regarded as 'income poor,' attempts to address their poverty as part of the social workers' interventions are usually short lived as the abuse becomes defined as 'individual agency' – a conscious 'commission' or 'omission' of an action.

Social workers should then ask how much choice people actually have. If the condition that someone has to live in generates exceptionally high levels of stress, and that the people living with this stress lack the financial resources to alleviate it – do they maltreat their children 'by choice'? In other words, is this a set of actions and behavior that represents a meaningful choice? Or, are the actions, at least to some extent, determined by the conditions people live in? Within a wider study of social policy, individual agency has often been treated with caution. Callinicos (2004) argued that all too often, attempts to impute individual agency to actions on its own seek to explain social phenomena through the lens of individual action, and, by focusing upon the individual action one can explain the social phenomenon. In the example of child maltreatment, which is a social phenomenon, the almost exclusive focus upon the agent of maltreatment allows for the actual social phenomenon and the social conditions that create it to remain unaddressed (Sidebotham et al., 2002).

This is not to suggest that all actions of maltreatment have their origins with structure or external factors, since clearly this is not the case – but the example serves to highlight the 'agency-structure' debate. The other side of this debate and social work's long connection with 'structure' will now be examined.

Choice as 'Empowerment'

If individual choice and self-determination finds it ethical underpinning in the work of Biestek (1961), and is based upon individual action, the exhortation for social workers and other welfare professionals to engage with structural factors equally has its ethical justifications. The International Federation of Social Workers' (IFSW's) ethical principles include the following in Section Choice as a 'Consumer,' entitled 'Social Justice':

> Challenging unjust policies and practices – Social workers have a duty to bring to the attention of their employers, policy makers, politicians and the general public situations where resources are inadequate or where distribution of resources, policies and practices are oppressive, unfair or harmful. (IFSW, 2012, http://ifsw.org/policies/statement-of-ethical-principles/)

This sets the question of empowerment within a political context. The writings of Marx identified the concept of 'consciousness' in relation to class as being a necessary precursor to any form of social change. Accordingly, Marxists seek to engender class consciousness among the working class to build labor solidarity. Thus, people are empowered by becoming aware of the power structures under which they live. This has a wider application, and for social welfare. Paulo Friere's 1970s work, *Pedagogy of the Oppressed*, although based in Latin America, had considerable influence in identifying the role and purpose of social workers 'raising consciousness.' Central to this is the idea that those working with oppressed and marginalized groups have a legitimate role in raising awareness of the structural factors that bring about their powerlessness and through this they (as the oppressed) can develop strategies to empower themselves. In short, this is not about social workers and other welfare professionals 'empowering' people, but rather ensuring that their actions bring about the conditions whereby such groups can engage in collective action. To develop the theme from the earlier section, social work as empowerment is not merely about individual agency, but significantly it is about enabling collective agency. This was a feature of the radical social work movement of the 1970s (see Bailey and Brake, 1975), the antiracist movement in the 1980s (see Dominelli, 1988a,b), and antioppressive practice in the 1990s (see Dalrymple and Burke, 1995). There is an equally strong trend in social work especially that sees 'individual' empowerment as a legitimate goal, often, as indicated earlier, with the aim of empowering service-users to make 'informal choices.' Empowerment within social work seeks to combine the concept of 'personal' empowerment with 'political' empowerment drawing from the radical social work literature of the 1970s and 1980s (Humphries, 1996).

This in turn connects to the development of new social movements (O'Brian and Penna, 1998) and, closely allied to this was the rise of service-user movements, which can be seen as an example of 'collective agency' or collective 'choice.' In such cases, service-users recognize their own individual agency alongside structures such as the disabling nature of society, highlighted by Michael Oliver (1990) and others in the disability rights field. Another important service-user group has been built around people who are, or who have, experienced mental ill-health and developed campaigns to assume control over their own lives. These activities, similar to those run by people with disabilities, focused around the concept that service-users should control their own services, and emphasized self-advocacy and drawing upon the experiences and accounts of 'mental health survivors.' This has often been a reaction against overly medicalized interventions, and has led to social workers regarding service-users as experts by experience, turning many service-users from passive recipients into active participants in service delivery.

Within a global context, collective agency and social work as empowerment is reflected in much of the community action work that has been developed. Furthermore, the global nature of social work draws more heavily on the idea of social work as empowerment than social work in the developed North, where community work, although it exists, often takes second place to an individualized personal agenda. Cox and Pawar (2006), in their study of international social work, also link empowerment to long-standing elements of community development work, and later to 'capacity building.' They emphasize the commonality of people and the desire to

acquire control over aspects of their environment, although they urge caution with the concept, since 'empowerment' clearly means different things in a range of contexts and their conclusion is that empowerment incorporates individual and group strategies, underscored by conscientization and social development processes.

Thus, empowerment is the coming together of individuals united by their social relations. Service-user movements have had a significant impact upon many aspects of social work and have, through collective responses, developed important alternatives to a more overtly individualized approach, and indeed, this was one of the foundations of the radical social work movement (Langan, 2002) and progressive community work (see also Loney, 1983).

Within the United Kingdom, a key movement is anti-oppressive practice, which began as a model of social work practice that was premised upon bringing about structural, as well as individual, change and reflected in the work of writers such as Dominelli (2002) and Dalrymple and Burke (1995), which developed ideas originally formulated by radical social workers during the 1970s. The model, however, was arguably appropriated by the mainstream and has often in practice been reduced to a series of interpersonal skills, such as enabling service-users to make informed (individual) choices, treating people with respect, and informing them of their 'rights,' in short what Dominelli (2000: p. 12) describes as 'bureaucratized forms of empowerment.' All these actions are good in themselves and it could certainly be argued that not to do this would be 'disempowering' and not conducive to 'choice' but that is quite distinct from these actions being part of an empowerment agenda.

Social work as empowerment takes the focus away from individuals and the type of case work codified by Biestek (1961), which emphasized various forms of casework and counseling. It remains, however, firmly rooted in the concept of choice, since collective action and collective work are the exercising of a shared and voluntarily engaged choice and will. It reinforces the concept of individual agency by ensuring that this is connected to structures and lays bare the false dichotomy of 'structure' and 'agency.'

Nonetheless, empowerment can be, and arguably has been, appropriated to maintain the existing order (Dominelli, 2000) and never is this clearer than in the next section, which examines the increasing role of the service-user as the customer and questions of consumer choice, prevalent in the United Kingdom and other developed welfare systems (Simpson and Connor, 2011).

Choice as a 'Consumer'

The beginnings of the twenty-first century saw a significant shift in the provision of services, in that those who received them (clients, service-users) began to be referred as 'consumers' or 'customers.' It is possible, within the United Kingdom at least, to see how this developed out of both the language of empowerment used by social workers and other welfare professionals, and service-user groups and movements (Ferguson, 2008).

This can be seen to connect readily with the idea of choice and empowerment when considering the use of large-scale institutions, particularly for people who were experiencing mental ill-health and those with disabilities. The so-called one-size-fits-all models began to disappear and the intention was that these were replaced with bespoke services; the service-user, therefore, became active in determining their service, rather than the recipient of an existing large-scale service: the latter became known as resources-led and was replaced by the 'needs-led' model. Thus, service-users identify their needs and, in theory at least, are offered choices to meet them. In short, the service-user becomes a consumer of services, although such approaches are not without their critics (Harris, 2003; Clarke, 2005).

This links to another form of choice, that is, the choices made by the consumer or more simply put, the buyer of goods or services. This draws on the economic theory of rational choice and is an attempt to move the consumerist ideology into a welfare setting. The person driven by rational choice as a consumer would fully research the product they wanted to buy (for example, a washing machine), be fully aware of the range of functions they wanted, and then make their decision based upon what the economist would call 'utility' either material or monetary (Seifert, 2011). Often the consumer will forego some functions for a cheaper model; at times, they may buy the best model, irrespective of price, dependent upon their economic position. While choice for the consumer is limited to what is available, the person acting upon their rational choices would maximize their options – they would not buy the first washing machine they saw. The rational choices of consumers will subsequently influence the producers of products because it is unlikely that a product that no one is likely to want to buy will be produced. If the producer continues to ignore the levels of market demand, according to classical economic theory (see Smith, 1976 [1776]) they would soon go out of business.

The extent to which this works in the actual retail market can be debated, but there are certainly difficulties when trying to apply it to welfare services. Those who support this development, for example, Glennerster (2009), point to its benefits. First, they would argue that the self-interest of the consumer, the mantra of 'I know what I want' is a more reliable mechanism for allocation than the goodwill of the provider. Second, they suggest that such a model brings into welfare the rigors of the market and ultimately a 'profit motive.' This will then result in more efficient, which social workers might say creative, solutions. Finally, and central to the whole consumerist ideology, is the notion of 'consumer sovereignty' or more colloquially, 'the customer is always right.' Partnership between those who buy and sell goods and services, or as is the case with a marketized form of welfare, between providers and users of services, is, therefore, important, not for the sake of 'choice,' but so that the market can accurately reflect service-user needs.

From the point of view of the service-user, the consumerist model is built upon 'choice' and services led by the 'consumer' rather than professionals. This will mean that services become more efficient in responding to their needs since continued payments depend upon it. Crucially, however, proponents of the model argue that consumers (service-users) need to be educated about the implications of their choices. This is akin to arguing that buying an energy-efficient washing

machine will be better for the environment in the long-run and this should be a factor in deciding the purchase. Yet, it is not hard to see how this process of 'education,' far from being the 'empowering tool' that in its purest form it might be, enables people to make the 'right' choices. Critics of the market approach embrace a range of positions but the factor that unites them all is that markets fail and choice is constrained (Glyn, 2006).

In the retail world, most people accept this as a social and economic reality, but, as Harris (2003) argues, social welfare is not amenable to market discipline. One knows where one can afford to shop and one also knows that some businesses fail, so one may not be able to continue buying a particular product. It becomes more problematic when this is transferred to the world of welfare, since markets do want to take high levels of risk, so people with high-level needs who are already vulnerable will be increasingly excluded. Within a profit-driven system, the social risks, which state welfare attempts to manage through welfare provision, become private and market-oriented risks. The desire for profit means that those who are at higher risk – generally poor people, people in poor health, and people with a disability – will not be catered for by such provision as the costs of doing so would result in low levels of return, diminishing profit (Esping-Andersen et al., 2002). Furthermore, by focusing upon individual preferences wider social needs may go unmet. Some writers (see Ferguson, 2008) have also suggested that the implementation of the market will result in a potentially alienated workforce, and the last thing service-users want is a workforce that does not engage with either them or their needs.

Perhaps the most significant aspect, however, of the consumer choice debate revolves around resources. It is perhaps a truism to argue that choices are limited by resources: either the resources that the customer has, or the resources available to produce the goods or services. In welfare terms where the market applies, people with greater resources will be able to pay for and receive a better type of service, whereas those who lack resources will be dependent upon the residual services provided – confirming that those already marginalized are likely to have this confirmed through market provision and not addressed by it, since the market is not designed to deliver universal services – for the simple reason that this will not generate an adequate return. Thus, for there to be genuine choice for all 'consumers' of social care, a full range of options would have to be equally available, almost certainly funded by the state either directly or indirectly.

The next section examines the question of choice as social policy – especially the dominant policy trend within neoliberalism.

Choice as Neoliberal Policy

Within the United Kingdom and much of the developed world, there has been a move toward the adoption of neoliberal economic policies. These are characterized by low rates of taxation and low levels of state expenditure with the attendant withdrawal of the state from provision leading to a general reduction in welfare benefits and more crucially state-led welfare provision. To a greater or lesser degree, this trend has affected all developed countries – although the extent to which governments have embraced such changes varies according to the political choices they make. This shift in policy has been accompanied by a language of choice, which is a key concept within the language of neoliberalism and, as was discussed in the last section, seeks to borrow concepts from the world of business and retail and apply or (in some instances) impose them upon service provision and welfare (Le Grand, 2007).

At one level, there can be at least notional gains for service-users as a result of such policies and the case of 'direct payments' within UK social policy is an example. The service-users receive a sum of money with which they can buy and organize the care and services they want, as opposed to having to receive services that exist and may not be tailored for their needs. In this way, it could be argued that the service-user, as a consumer, is 'empowered.' Yet, even this is not a straightforward transaction, shaped by assessment and, crucially, limits upon funding. Any analysis of policy, however, needs to understand the underlying aims and to this end, it is important when considering the 'choice as policy' to analyze the aims and policy beneficiaries.

Recent trends, notably within the United Kingdom, have seen the language of 'choice' being used to introduce a whole series of 'reforms' that have been linked to the economic policies of neoliberals, and that have frequently resulted in policies designed to bring about reductions in services. In a study of people with a moderate to severe learning disability, Simpson and Price (2010) suggested that policies designed to improve social inclusion had often resulted in greater levels of social exclusion for this service-user group, particularly those whose needs were the most demanding of support. Their conclusion, echoing Scull's (1983) in relation to mental health, was that when social liberal policies meet liberal economic policies, the social liberal view is appropriated for a political end. Further, in his review of these developments, Stan Houston (2010) identified the provision of services being driven by the idea of the *homo economicus* – the economic rational actor of rational choice theory, making decisions based upon a distinctly economic calculation. More recently, in his review of policies relating to well-being, Simpson identified 'choice' as a dominant factor in determining services. He located this within a wider discussion of the different factors that contribute to a person's sense of well-being, where choice is but one of several other more important factors identified by Robert Schalock (2004), which gave greater emphasis to friendships and relationships, community engagement, and wider structural factors that impact upon people – yet, increasingly social work policy and practice privileges 'choice.'

Choice, therefore, has moved from being a social work value based upon 'self-determination' to the rationale underpinning policy shifts – shifts that do not promote actual choice but rather to 'semblance of choice' within increasingly limited options. In one sense, 'choice' becomes part of a dominant policy hegemony, the overarching principles that shape the ways in which services, social work, and social policies surrounding social welfare are discussed. To be able to 'choose' between schools, hospitals, or social care services is seen a progressive empowering and part of what Clarke (2005) argued was the making of the 'citizen

consumer.' The combination of the ideas around 'choice' discussed earlier – self-determination, empowerment, and consumer sovereignty – can all be combined in this series of dominant ideas that shape expectations, and by invoking choice as part of new policies, it acts as a convincing cloak to hide realities of reduced services.

'Choice' and Collective Action

In the previous section, the manner in which 'choice' is spoken about focuses upon the individual and thereby 'individualizes' choice. The development of this into a very clear political framework both rests upon and encourages this level of individualization. The final section will examine how individuals can 'choose' to engage in collective action, which offers a different perspective to the individualized hegemony, which is common to most discussions of 'choice.' To begin with, the concept of 'agency' will be reconsidered.

Agency is significant both for groups and individuals. Not only does agency allow for 'choice' but it also allows for the social movements of, for example, people with disabilities, to campaign for greater levels of choice and control over their lives. For people who are engaged in social work practice, or indeed any social welfare practice, they do so often at an individual level – as individuals and of course, with individuals. Simpson and Connor (2011) examined the question of policy and agency in some detail. They argued that individual practitioners needed to understand their own and their service-users' position within the wider remit of social relations and structures. When considering 'choice,' this cannot simply be located within an individualized account, standing outside of political and social factors. Callinicos (2004) has argued that such traditional models of choice result in explanations of social phenomena through the actions and motives of individuals. Thus, agency and, by extension, choice have to be understood within structures.

It has already been argued that 'choice' is limited by social position or economic standing – in short, the more money you have, the more choices you have. This would lead to potential and actual unequal distribution of resources. Within social work, the IFSW's ethical principles include the following:

> Social workers have a duty to bring to the attention of their employers, policy makers, politicians and the general public situations where resources are inadequate or where distribution of resources, policies and practices are oppressive, unfair or harmful. (2012, http://ifsw.org/policies/statement-of-ethical-principles/)

To do this alone is to risk failure and so such challenges need to be part of collective action. To engage in collective action is, in the first instance, an act of individual will – or choice. A clear example here is that of service-user movements. A Marxist approach would argue that action is both an individual and collective choice, and that often there is a desire to hide the inherent social relationship by recasting those who challenge the social order in collective ways as being 'heroes' or people who have made a 'special contribution or achievement.' In such ways, the actual order is not challenged and the individualized nature of choice persists.

Choice then provides not only potential opportunities for people but also specific challenges. Within an unequal structure, choice allows for the 'hope' of greater 'freedom' while actually concealing the realities of diminishing choices and resources. Those who are engaged in social work and social welfare need to understand the appropriation of choice into a particular set of social relationships, which maintain social, economic, and power differentials. If choice is to be fully embraced as 'empowerment' by and for people who lack these resources, then it needs to be within the concept collective choice, will, and action.

This not only has a 'local' application within established welfare regimes. One of the key challenges for social work internationally is to harness the potential of local communities in collective responses to the difficulties they face, including the nature and work of nongovernmental organizations. It could be argued that developed 'northern' regimes have premised much of their provision upon a particular concept of 'choice,' whereas cultural and social organization in the developing 'South' should be one that allows for indigenous people to have the 'choice' to develop their own welfare futures. Much international work is development within a specific 'Northern' tradition. This can involve the imposition of particular methods and expertise that have their origins elsewhere upon those who have a different world view. Such an expression of social work, set out in Cox and Pawar's (2006) text, is a vital and necessary antidote to the seemingly relentless spread of global capital in its search for new markets and resources.

Conclusion – What Type of Social Worker?

This article has explored the concept of choice within social work, welfare, and policy. In doing so, it has introduced different notions of how 'choice' can be understood within social work and policy. It has drawn mostly from developments within 'northern' welfare regimes, which in the decade 2010 are experiencing significant reductions in welfare and services, which impact upon those who have the least resources and therefore often the fewest choices.

There has been a focus upon some of the more traditional aspects of choice, many of which see choice as progressive but there has also been an exploration of challenges to and critiques of these notions. A concluding comment is that those who enter social work, and any other welfare profession, also have to make 'choices' and answer the question of what kind of worker they want to be. Ferguson's work *Reclaiming Social Work* sets out a new agenda for engaged practice that offers a response to this question within a social work context.

Simpson and Connor argue that this is not 'straightforward,' but, drawing upon the work of Ledwith in 2007, two broad 'alternatives' can be identified. One is the technician, who possesses a range of skills and knowledge, brought to bear on a problem in a rational technical manner, and who aims to 'improve' things for people within the existing frameworks. Arguably, technicians attempt to preserve professional autonomy and freedom, but perhaps do not question the nature of the organization (and ultimately the state) they are employed by. The contrasting position is that of the activist, who also believes that the skills and knowledge gained should

be used for improvement but they will not only deal with the symptoms of injustice but also seek to address the underlying structural causes of this. That then remains the final challenge of 'choice' outlined in this article.

Abstract

This article offers an overview of Noam Chomsky's contributions to linguistics, as well as the multiple fields that are impacted by his approach, including psychology, philosophy, computer sciences, communications, political studies, neuroscience, and behavioral sciences. The emphasis is placed upon his early formative years, the milieus from which he emerges and to which he contributes, and the general attitude that drives his work, right up to the current moment.

Avram Noam Chomsky was born in Philadelphia on 7 December 1928, to Dr William (Zev) Chomsky and to Elsie Simonofsky. William Chomsky, who came from Russia to the United States in 1913, was a Hebrew scholar that the *New York Times* referred to, in an article that appeared on 22 July 1977, as 'one of the world's foremost Hebrew grammarians'. Elsie Simonofsky taught Hebrew at Mikveh Israel, for which William Chomsky was the Principal.

Noam Chomsky grew up in Philadelphia with his parents and his younger brother David, who eventually studied medicine and became a doctor in Philadelphia. The whole family was actively involved in Jewish issues, notably the revival of the Hebrew language, Jewish cultural activities, and Zionism. Noam read Hebrew literature with his father, spent a considerable amount of time in Hebrew school, and later became a Hebrew teacher. Although his parents were 'normal Roosevelt Democrats', he had cousins and uncles who were part of a Jewish working class with ties to various strains of communism. The neighborhood in which Chomsky was raised consisted largely of Germans and Irish Catholics, who Noam recalls as being largely anti-Semitic and pro-Nazi.

From just prior to his second birthday, he was sent to the Oak Lane Country Day School, where he remained until the age of 12. The pedagogical approach taken at this Deweyite experimental progressive school remains for him an oft-recalled model, since it brought together students with different levels of talent, from various backgrounds, and fostered their creative faculties without a competitive system of evaluation. This approach placed a premium upon creativity, and since no one activity was put forth as the standard, each student was encouraged to believe in the value of his or her own activity, so that if competing at all, students were competing with themselves. This kind of thinking still underwrites both his political and linguistic writings, as well as his teaching, emphasizing stimulation of potential through noncoercive social structures. While at this school Noam began writing for the school newspaper, and his first piece appeared shortly after his tenth birthday, when he contributed an editorial on the fall of Barcelona. The impact of the Spanish Civil War is still present in many of his political articles, because this revolution makes manifest the idea that people can organize spontaneously, without a vanguard, to combat systems of oppression. The period leading up to this kind of action, though, required organization and a commitment education and militancy, ideas promoted by the New Left, for which Chomsky remains a leading figure.

He was from an early age a voracious reader in many fields. In terms of literature, for example, early influences included Tolstoy, Dostoevsky, Turgenev, Eliot, and Dickens, as well as the Bible (largely read in Hebrew), and Yiddish-Hebrew writers of the late nineteenth and early twentieth centuries. At the age of 12, he read the proofs for his father's book on David Kimche (1160–1236), a Hebrew grammarian working in the thirteenth century, during the so-called Golden Age of Jewish cultural creativity. This experience provided a philological background, although his eventual aim in his linguistic work steered clear of the search for meaning in favor of descriptive explanations, aimed at providing a theory of the synchronic structure of the language which would explain the distribution of phenomena. Insights concerning the value of forgotten learning and the importance of language studies are both reflected in Noam Chomsky's later work, in particular in books such as *Cartesian Linguistics*. Of the influence of his readings in Jewish texts, though, he recalls a special fondness for the Agadah, the legends of stories, rather than the Talmud, which he did study but which played no special role in his development.

At the age of 12, Chomsky entered the Central High School in Philadelphia, a traditional public school, where a heavy premium was placed upon academic success through imposed curriculum, hierarchies of knowledge and students, and a mainstream system of values that he described as impediments to independent and creative thinking. He was an active and well-liked student at Central High and belonged to numerous clubs and read voraciously. Nonetheless, intrigued by libertarian anarchist movements, and knowledgeable of events in Spain, he was by 1941 making regular trips by train by himself to New York to visit relatives and second-hand bookstores on Fourth Avenue. He also frequented the *Freie Arbeiter Stimme* office, the place from which was published an anarchist journal to which notable influences, such as Rudolf Rocker (a crucial interlocutor), contributed. He also spent a lot of time with a relative of his in New York, an uncle (on his mother's side), who ran a newsstand on 72nd Street that served as an informal literary political salon.

In 1945, Chomsky began undergraduate studies at the University of Pennsylvania. He continued to live at home, paying for his education by teaching Hebrew school in the afternoons, on Sundays, and sometimes in the evenings. His enthusiasm for university rapidly waned, however, when he found that the institutional structure he so loathed in high school was largely replicated at Penn. He did meet scholars

who were to be influential for him, including C. West Churchman in philosophy, and Giorgio Levi Della Vida, who taught Arabic, and in 1947, while still an undergraduate, he met Carol Doris Schatz (1930–2008), whom he'd first met at Hebrew School when he was seven. Noam and Carol Schatz were married in 1949, and in 1953 they stayed on an Israeli kibbutz. They had considered moving there, but found a high level of ideological conformity to Stalinist ideology. After 6 weeks in Israel, they returned to the US, and shortly after started a family, and so Carol interrupted her studies in order to raise the children. She later returned to complete her work in linguistics, and went on to a linguistic career of her own, eventually securing a position at Harvard's School of Education, where she specialized in language acquisition. She has also worked on language abilities in deaf-blind subjects in the Sensory Communication Group of the Research Laboratory of Electronics at the Massachusetts Institute of Technology, and has studied the invented spelling of children who began writing before learning how to read (published in 1979). She also became active in Noam's political work, helping to assemble materials and organize clippings for the huge database from which Chomsky draws for his writing.

In addition to meeting his lifelong partner in 1947, Chomsky also met Zellig Harris, who shared many of his interests and had overlapping interests with Noam's father on issues relating to the Hebrew language. Noam had met Zellig Harris in the Harris family home, since Zellig's father regularly held Jewish services in the basement to which he had on occasion invited the Chomsky family. Harris asked Chomsky to read the proofs of a manuscript called *Methods in Structural Linguistics*, but it was not Harris's linguistics that first attracted Chomsky, but rather his politics, and beginning in 1947 they developed a relationship that would be of great consequence to the field of linguistics. Harris also encouraged Chomsky to take graduate courses in philosophy, with Nelson Goodman, Morton White, and mathematics, with Nathan Fine, and he introduced him to psychoanalysis, and to the Sullivan–Horney–Rappaport school of psychoanalysis. The upshot of this connection to Harris was to lead Chomsky back to the unstructured, lively, and creative debate that had been characteristic of his early education and upon which he had thrived in the company of his uncle in New York. Harris shunned course requirements, formal relationships, and scholarly hierarchies in favor of informal gatherings, broad-based discussions, and intellectual exchanges in a range of fields.

Through the course of these meetings and his varied studies, Chomsky ultimately received his BA from the University of Pennsylvania, which turned around his interests in linguistics, philosophy, and logic. His BA honor's thesis, which set the stage for some of his later work and which is taken to be the first example of modern generative grammar, was completed in 1949. He then wrote a Master's thesis, completed in 1951, that was a revision of the BA thesis. It was further revised and then published in 1979 as *Morphophonemics of Modern Hebrew*. Chomsky described Harris's work during this period as a set of procedures for organizing texts, and his own early work in linguistics as trying to make Harris's methods work. His undergraduate thesis also applied some of Harris's ideas, aimed, most notably, at enriching the system of phrase structure rules by introducing complex categories with features that can percolate downward to the categories contained within them, expressing global dependencies not captured in a simple system of phrase structure rules. This was already an approach that deviated from the dominant features of contemporary structuralist linguistics, although Chomsky did receive encouragement from Israeli logician Yehoshua Bar-Hillel, a colleague of Carnap's who became a close friend to Chomsky beginning in 1951. Henry Hoenigswald, a linguistics professor at Penn who focused on historical linguistics and the Indic tradition, also read Chomsky's work during this period.

In 1953, Chomsky broke from the prevailing structuralist methods of the time by suggesting that linguists should abandon their quest for discovery procedures, and pursue the task of finding evaluation procedures, which he himself elaborated in a framework that came to be known as principles and parameters. This led Chomsky to a break from Harris beginning in the early 1950s and definitively when he abandoned the *Methods* program a few years later.

Much of what would later be considered Chomsky's major contribution to the field was undertaken early in his career and recorded in *Morphophonemics*, his 1956 paper with Halle and Lukoff, his contribution (unpublished) to the 1959 Texas conference (in terms of contemporary generative phonology) and the linguistic parts of *Logical Structure of Linguistic Theory* (LSLT) (in terms of syntax-semantics). And the advancements he and those who follow his approach have made since that time owe much to the radically divergent path that he chose to follow – even as an undergraduate (cf *Morphophonemics*). *Syntactic Structures*, published in 1957 (the year in which he was also a visiting professor at Columbia University, invited by the Yiddishist and early sociolinguist Uriel Weinreich). The aim of this work was to develop a grammar which is able to *generate* sentences, just as the speaker of a language is able to produce a virtually infinite number of sentences (*performance*) using the finite number of words and grammatical rules known to him (*competence*). Another crucial work at this time was his review of B.F. Skinner's 1957 book *Verbal Behaviour*. Skinner, the leading proponent of behaviorism, believed that human behavior, and in particular verbal behavior, can be explained and controlled by the same external processes (reinforcement, for example) as those employed to predict and control the behavior of animals. This in Chomsky's view denies a fundamental characteristic of human behavior, creativity, which allows even very young children to comprehend a great variety of utterances *even if they are hearing them for the very first time*. Furthermore, the application to language processes of behaviorist psychology terminology, such as 'stimulus', 'response', 'habit', 'conditioning', and 'reinforcement', was by Chomsky's reading so loose that it could cover virtually anything, and was thus devoid of empirical content.

Chomsky's viewpoint here is ostensibly situated within a *rationalist* perspective, the tenets of which look back to views developed during the seventeenth century, a connection he would make in his second linguistic study, *Cartesian Linguistics*. Therein, Chomsky traces the Cartesian viewpoint through the Enlightenment and the Romantic period, emphasizing its value in terms of understanding creative discourse. He ultimately dwells upon the work of Wilhelm von Humboldt whose work on linguistics and his postulations with regards to appropriate societal makeup correspond very strongly to Chomsky's own

approach. Humboldt's vision, taken up in various ways in other Enlightenment thinkers, is another kind of *leitmotif* in the work of Chomsky that appears, for example, in his various discussions concerning 'language and freedom'. In a lecture, delivered to the University Freedom and the Human Sciences Symposium on 8–9 January 1970, Chomsky reiterated the language–freedom relationship with regards to historical texts, notably works from the Enlightenment period. Citing Rousseau (especially his *Discourse on Inequality*, 1755), Kant, Descartes, Cordemoy, Simon Linguet, and Humboldt, Chomsky describes the Enlightenment vision of a society set up to encourage rather than stifle human potential. Humboldt is particularly important here because he makes the link between characteristic human traits, an appropriate social setting and the language that sets man apart from animals.

In 1958 Chomsky was promoted to Associate Professor at MIT, and in 1958–59, he was a National Science Foundation Fellow at the Institute for Advanced Study at Princeton which gave him the opportunity to revise LSLT, and to participate once again in the Texas Conferences on Problems of Linguistic Analysis in English in 1959. In the spring of 1959, he then began working on a project involving generative phonology, applying to the English language work that he had previously undertaken in Hebrew as *Morphophonemics of Modern Hebrew*. By the early 1960s, his work had gained him recognition in linguistics, philosophy, and psychology. This growing eminence was in part the result of his having begun a graduate program in linguistics and philosophy at MIT with like-minded colleagues (notably Morris Halle and the first Chair, Jay Keyser). The program attracted a number of gifted scholars during this period, including Robert Lees, Jerry Fodor, and Jerry Katz, graduates of the PhD program at Princeton and Paul Postal, who completed his PhD at Yale. All were eventually named to the MIT faculty; Postal in linguistics, Fodor and Katz in philosophy.

The early to mid-1960s was a time of enormous production; in 1962 he gave a paper, at the Ninth International Congress of Linguists, entitled 'The Logical Basis of Linguistic Theory', which outlined an approach to language known as 'transformational generative grammar'. In June of 1964 Chomsky also gave a series of lectures at the Linguistic Institute of the Linguistic Society of America, which were published in 1966 as *Topics in the Theory of Generative Grammar*. He published *Aspects of the Theory of Syntax* (1965), and *Cartesian Linguistics: A Chapter in the History of Rationalist Thought* (1966). He gave a set of lectures to a general audience, in Berkeley, in January of 1967, which were enlarged and published as *Language and Mind* in 1968 (enlarged with several later essays added, in 1972). And he completed *The Sound Pattern of English* with Halle in 1968. He wrote it during a period in which he was a Fellow of the American Council of Learned Societies with the assistance of the National Institutes of Health at Harvard University, the Centre for Cognitive Studies, and a grant from the Social Science Research Council, and he presented his findings prior to publication in the Christian Gauss seminars in Criticism at Princeton, a series of six weekly lectures.

In 1966, Paul Lauter contacted Chomsky (who at that time had been trying to organize national tax resistance with his friend Harold Tovish, a well-known sculptor) and asked him to team up with him to lend support to draft resistance. The result was a group called Resist, which eventually came to be involved in other forms of resistance to 'illegitimate authority', and which came to be associated with such people as Dwight Macdonald, Dr Benjamin M. Spock, and Reverend William Sloane Coffin. So while he was assembling the Beckman lectures for eventual publication as *Language and Mind* (1968), which traces historical developments concerning the study of language and mind with particular reference of rationalist philosophy, he was also working on a series of political articles. 'Responsibility of Intellectuals', his first (of numerous) articles published in the *New York Review of Books* (*NYRB*) created considerable interest because of the large readership of *NYRB* and the type of audience drawn to such a paper at that time. The contributions to NYRB brought to the fore Chomsky's public persona, his power as political renegade, and would, especially with the publication of his book called *American Power and the New Mandarins* set the stage for his being associated with the vocal dissenting left on the American scene.

By the early 1970s Chomsky, now in his early 1940s, continued to lecture, to receive honors, and to hone his linguistic works. He published *Studies on Semantics in Generative Grammar* in 1972, and received honorary Doctor of Humane Letters from five prominent universities. But at least outwardly, he was increasingly active on the political scene, giving the Russell Memorial Lectures in Cambridge in 1971, and publishing, *At War with Asia* in 1970, *Problems of Knowledge and Freedom* in 1971 (the Russell Memorial Lectures), and *For Reasons of State* in 1973. The basis of much of his political work during this period, aside from his interest in the relationship between the intellectual and the state, was the Vietnam War.

Within the field of linguistics, and specifically in Chomsky's department at MIT, the late 1960s marked a period of dissension and tension among faculty and students. An article called 'Former Chomsky Disciples Hurl Harsh Words at the Master', which appeared on 10 September 1972 in the *New York Times*, describes dissident activities within the department. This schism in the field generated significant discussion and 'linguistic wars' that came to be discussed quite publicly, and generated considerable work. At the same time, in the mid- to late 1970s publications such as *Reflections on Language* (1975) and *Essays on Form and Interpretation* (1977) appeared (as did LSLT, although it had been written in 1955–56), and studies that Chomsky had been working on for years entered the public domain.

Chomsky always lectured widely, and during this period alone he gave the Whidden Lectures at McMaster, the Huizinga Memorial Lectures at Leiden, the Woodbridge Lectures at Columbia, and the Kant Lectures at Stanford, and he was named as Member of the British Academy in 1974. But it was the *Reflections on Language* book that probably created the greatest amount of discussion within the field, at least in part because of John Searle's review article 'The Rules of the Language Game', that appeared in the 10 September 1976 *Times Literary Supplement*. In Searle's opinion, *Rules on Language* (*RL*) confirms a retreat from Chomsky's previous positions, in particular the idea that a sentence's meaning is determined by its syntactical deep structure. The book that Searle was discussing was comprised in part of the Whidden Lectures, which addresses the first of three problems that Chomsky has elaborated in various discussions; this problem, which Chomsky has called 'Plato's problem', that can be described in terms of the

question of why it is that humans, whose contact with the world are brief and limited can come to know so much. The second problem, more often taken up with regards to political rather than linguistic discussions, is what Chomsky called Orwell's problem, asking how is it that human beings know so little given the amount of information to which they have access? And the third, which he refers to as Descartes' problem, relating to mysteries for humans, categories of knowledge that seem to lie beyond epistemic bounds.

Chomsky's political work during this period continued to focus upon issues that he had talked about since the late 1960s and early 1970s, including the Middle East, the Spanish Civil War, the backgrounds to World War II, the framework of US global planning, global order, and Indochina. But he was paying special attention to the question of why, after almost a century of destruction and invasion that had been unusually heavily reported (as a result of new technologies), and after recent events which should have shaken American confidence in their institutions, the society did not rise up (an issue that was in his work related to discussions of historical and ideological reconstruction). On the contrary, the spirit of dissent of the late 1960s and early 1970s was, at least on the surface, becoming a spirit of resigned consensus. At this point, Chomsky began to collaborate with the next person in the milieu, Edward S. Herman, who had similar interests and who had also published books on the Vietnam War in 1966 and 1971. The Chomsky–Herman collaboration would ultimately lead to the publication of several articles and books, including *Counter-Revolutionary Violence* (1973), *The Political Economy of Human Rights* (1979), and *Manufacturing Consent* (1988, the title later adopted to the film *Manufacturing Consent: Noam Chomsky and the Media* by Achbar and Wintonick, and the companion book edited by Achbar). Texts published from this time forth, notably *Language and Responsibility* and *Radical Priorities*, also contain wide-ranging discussions covering the many disciplines that have interested Chomsky since his youth and that continue to be impacted by his work. Chomsky added substantially to his growing corpus during this period with the publication of *Human Rights and American Foreign Policy* (1978), *Language and Responsibility* (1979), and, once again with Edward S. Herman, *Political Economy of Human Rights* (1979).

Out of the sheer volume, vociferousness of the critique, and the radical underpinnings of his approach, Chomsky's political talks during this time stirred up considerable controversy from different sectors. His criticism of American policies in Vietnam and Cambodia had alienated him from establishment intellectuals and politicians, his condemnation of Cold War policies led to his continued ostracization by the proponents of America's 'free world' policies, and his ridiculing mainstream American's propaganda-instilled description of the 'free world' has led to significant efforts to question or ignore his work, which continues to this day. But this period was particularly fraught, marked as it was by two controversies, relating to Chomsky's having signed a petition on behalf of Robert Faurisson, that led to the 'Faurisson Affair', and his (along with Herman's) comparison of the relative number of innocent people killed by Pol Pot in Cambodia and by the Indonesians in East Timor, and the reporting thereon, that demonized Pol Pot and ignored East Timor. The East Timor example demonstrated the ways in which Western powers can ignore their own complicity while playing up the aggressions of the enemy, but this was construed as his being an apologist for Pol Pot's atrocities. He also added during this period a series of books including *Reflections on Language* (1975), *Essays on Form and Interpretation* (1977), *Rules and Representations* (1980), and *Modular Approaches to the Study of the Mind* (1980). These works include essays and lectures which expand and clarify previous work, address issues raised by his critics, update grammatical theory based upon recent work (by Chomsky and others), and all the while developing the thesis that language (and other mental abilities) should be seen as 'growing' in the individual's mind, under genetic control, rather than as 'learned' by organisms lacking any initial predisposition to develop the particular kinds of mental faculty which are eventually acquired.

Chomsky's linguistic work made important progress in the early 1980s leading him to what has been described as a 'new programme', the products of which are recorded in *Lectures on Government and Binding* (1981), *Knowledge of Language: Its Nature, Origin, and Use* (1988), *Barriers* (1988), and finally, in a more accessible form, in *Language and Problems of Knowledge: The Managua Lectures* (1988), which also includes some political discussion arising out of questions posed by the audience in Managua. More recently is *The Minimalist Program* (1995), the work that has taken shape around questions that came into focus in 1980 with the Principals and Parameters model. These texts offer significant advances in the field, offering insights into "empty categories and the principles that govern them, and that determine the nature of mental representations and computations in general, as well as the principles of phrase structure, binding theory, and other subsystems of universal grammar". Chomsky described these developments as part of a revolution in our understanding of the human mind, a leap forward that for him was akin to some of the scientific discoveries of the seventeenth century.

The political work continued to evolve on a tack consistent with principles previously described, but broadened to address a larger number of issues, including expanded work on media research (*Manufacturing Consent: The Political Economy of the Mass Media*, 1988, with Edward S. Herman, *Necessary Illusions*, 1989), Cold War, post–Cold War, and terrorist-style politics (*Towards a New Cold War. Essays on the Current Crisis and How We Got There*, 1982; *Pirates and Emperors: International Terrorism and the Real World*, 1986; *The Culture of Terrorism*, 1988; *Terrorizing the Neighbourhood: American Foreign Policy in the Post–Cold War Era*, 1991; *World Orders Old and New*, 1994), Israel (*The Fateful Triangle: The United States, Israel and the Palestinians*, 1983), Latin America (*Turning the Tide: U.S. Intervention in Central America and the Struggle for Peace*, 1985), Vietnam (*Rethinking Camelot; JFK, the Vietnam War and US Political Culture*, 1993), and imperialism (*Deterring Democracy*, 1992; *Year 501: The Conquest Continues*, 1993). Two popular 'readers' were also published during this period, *Language and Politics* (1988) and *The Chomsky Reader* (1987), two introductions to Chomsky's work were written by Carlos Otero, and collections of interviews such as *Chronicles of Dissent* (1992) and *Keeping the Rabble in Line* (1994) and, more recently, *Understanding Power: The Indispensable Chomsky* have given the reader access to interviews on wide-ranging subjects. This (incomplete) list is itself evidence that a synopsis of Chomsky's work over even

a relatively short period could but scratch the surface of a very deep corpus. Chomsky's many accomplishments earned him admiration from his peers, who rewarded him with such honors as: the Distinguished Scientific Contribution Award, American Psychological Association (1984), the Kyoto Prize in Basic Science, Inamori Foundation (1988), the Orwell Award, National Council of Teachers of English (1987 and 1989), he was made an honorary Member, Ges. Für Sprachwissenschaft, Germany (1990), and he became a William James Fellow, American Psychological Association (1990), and so on.

Whole generations of scholars have been trained by Noam Chomsky and as well by Carol Chomsky, and their own three children; their oldest child, Avi, is a Professor of Latin American history; their second, Diane, has for a long time lived in Managua; and Harry Chomsky works in the computer field on the West Coast. Carol Chomsky worked for 25 years at the Harvard Graduate School of Education, where she taught courses on language and linguistics; she eventually transferred to technology and education, with which she had been involved for years. She passed away in 2008. Chomsky's ideas continue to evolve, and to have had a strong influence on researchers in virtually every discipline in the humanities and social sciences, as well as in neuroscience, computer science, and emerging work that study the brain. As such, he has a very public persona, enhanced as well by notable debates over the years, with William F. Buckley, Alan Dershowitz, Michel Foucault, Christopher Hitchens, George Lakoff, Richard Perle, Jean Piaget, Hilary Putnam, Willard Quine, John Maynard Smith, and others, including Ali G. His recent honors include a 2005 honorary fellowship from the Literary and Historical Society; a 2007 Uppsala University Honorary Doctor's degree in commemoration of Carolus Linnaeus; the President's Medal from the Literary and Debating Society of the National University of Ireland; and a 2010 Erich Fromm Prize in Stuttgart, Germany. Also in 2010, Chomsky became the third scholar to receive the University of Wisconsin's A.E. Havens Center's Award for Lifetime Contribution to Critical Scholarship. He was voted the leading living public intellectual in The 2005 Global Intellectuals Poll; in a list compiled by the magazine New Statesman in 2006, he was voted seventh in the list of 'Heroes of our time'; and on 22 January 2010, a special honorary concert for Chomsky was given at Kresge Auditorium at MIT, featuring music by Edward Manukyan as well as honorific speeches from Chomsky's colleagues. In June 2011, he was awarded the Sydney Peace Prize and, also in 2011, he was inducted into IEEE Intelligent Systems' AI's Hall of Fame for his contributions to the fields of Artificial Intelligence and Intelligent Systems. In 2012, he played a deadpan cameo role in 'MIT Gangnam Style', a parody of the 'Gangnam Style' music video that became one of the most popular on YouTube. And most recently, in 2013, a newly described species of bee was named after Noam Chomsky: Megachile chomskyi.

Abstract

There are approximately 85 million Christians in Asia but more than 40% of them live in just two countries, the Philippines and South Korea. In the postcolonial era, a strong element of Christian social militancy was observable in many Asian countries. Postcolonial Asian Christian social protest has focused on various concerns including the continuing social power of caste in India, workers' rights in South Korea and Southeast Asia, and democratic reform of authoritarian political regimes which characterize government in much of the region. A more recent form of militancy in Asian Christianity is associated with the rise of charismatic/Pentecostal and fundamentalist/evangelical groups. Asian Christians now find their claimed freedoms to worship and evangelize occasions under increased social scrutiny and resistance among majority religious and cultural groups and their political leaders

Christianity in Asia has an ancient history though it remains a minority religion. There are approximately 85 million Christians in Asia but more than 40% of them live in just two countries, the Philippines and South Korea. The minority status of Christianity in Asia gives it a distinctive sociological character in relation to Christianity in other regions of the world. For many Asian theologians this distinctive sociological context has meant that the particular focus of their articulation of the Christ of Asia is that of dialogue with the dominant religious and cultural traditions of Asia. In the postcolonial era a strong element of Christian social militancy was observable in many Asian countries. This militancy was associated with the ecumenical Christian Council of Asia, and especially its sponsorship of Urban Rural Mission in a number of countries. The Catholic Federation of Asian Bishops Conference is also an organization which has confronted frequently social and political controversies in particular Asian countries. Postcolonial Asian Christian social protest has focused on various concerns including the continuing social power of caste in India, workers' rights in South Korea and Southeast Asia, and democratic reform of authoritarian political regimes which characterise government in much of the region. A more recent form of militancy in Asian Christianity is associated with the rise of charismatic/Pentecostal and fundamentalist/evangelical groups which have arisen within and beyond the denominational boundaries and institutions established during the colonial era. Adherents of the new charismatic and evangelical forms of Asian church regard Christian worship, spirituality, and personal evangelism, rather than social transformation in the wider society, as the essential vocation of Asian Christians. This more transcendental and salvific emphasis represents a clear rejection of the social protest of earlier forms of postcolonial Asian Christianity. The new militancy is more focused on claims to spiritual power for the new forms of Asian Christian spiritual and congregational life, and the rights of all Asian Christians to freedom of worship, and to proselytise their neighbors. Just as the earlier ecumenical and socially radical militancy was the occasion for formal State resistance in South Korea in the 1970s, and in Singapore, Malaysia, and Hong Kong in the 1980s, so Asian Christians now find their claimed freedoms to worship and evangelize occasion increased social scrutiny and resistance amongst majority religious and cultural groups and their political leaders.

South Asia

There is evidence of Christian activity in South India and Sri Lanka from the sixth century. Kerala is the region where most activity was concentrated, and Christians are still strong there, comprising 20% of the population. Christians also comprise a significant proportion of the population of Tamil Nadu. Portuguese colonisers saw a connection between trade and religion and, with the aid of the Jesuit order, encouraged the majority of the population of their settlement in Goa to convert to Christianity by the end of the sixteenth century. Under British rule the East India Company resisted the deployment of missionaries, judging that their presence would exacerbate existing religious tensions between Hindus and Muslims. But in the nineteenth century missionaries were allowed into most of British India. Converts were few and most were from marginal tribal groups, or from untouchables who have much to gain by abandoning Hinduism for Christianity. Since the 1980s a vocal Dalit (untouchable) movement has emerged which is radically anticaste and draws on Latin American-style liberation theology for its inspiration. With the rise of religious politics in India since the Premiership of Mrs Gandhi, religious conflict has become endemic in many parts of India and this has had an increasing impact on Christians. In Sri Lanka Christians are most prominent in the West and make up 30% of Colombo's population.

Christianity in China

Christianity in China goes back to the migration of Nestorian Christians from Iraq to China along the trade routes in the seventh century CE. The Jesuits arrived in China in the sixteenth century under the leadership of Matteo Ricci who experimented with a radical indigenisation of Christianity to Chinese culture. His efforts at cultural translation were controversial in Rome and the Pope insisted on a reversion to Roman rituals and

traditions in 1744. After the opium wars and the Nanking treaty of 1842, Catholic and Protestant missionaries settled in many parts of China. The association between Christianity and Imperialism was strong and conversions were few until the failure of the Boxer rebellion at the end of the nineteenth century when many, especially young, Chinese turned to Christianity as a potential source of social and spiritual restoration. With the advent of Communist government in 1949 all foreign missionaries were removed from China and churches closed. Ironically the exclusion of foreign missionaries allowed Chinese Christianity to flourish in a way it had not before and the Christian presence in China today is much greater than it was at the time of the Communist revolution. Most of the officially recognized churches in China, whether Catholic or Protestant in origin, are known as three-self churches, which means that they are not dependent on extra-Chinese ecclesiastical authority, nor do they rely on funds from overseas. There are also a large number of unofficial churches and congregations in China whose leaders try to circumvent controls on officially recognized churches, and in particular controls on proselytism. Evangelistic and worship meetings are held in secret, in apartments, or in open spaces away from city or town centres. The mass migration of many tens of millions of rural migrants into towns and cities in China since the 1980s, the largest contemporary movement of people on the planet, has occasioned conversions to new religions, including Christianity, as migrants seek to find a substitute for village-folk religion. Churches in urban areas, and especially in southern China, are currently growing very fast, fuelled by the spiritual and ritual vacuum occasioned by the Cultural Revolution and the enforced break-up of traditional Chinese religions, and by intellectual and popular dissatisfaction with secular Communist ideology.

Hong Kong, Taiwan, Japan, and Korea

One fifth of the population of Hong Kong are Christian and just under half are Catholics. The principal Protestant and Catholic traditions are represented and there are also a large number of independent and Pentecostal churches which have become established since the 1970s. The majority of Christians in Taiwan are Presbyterian, reflecting a missionary drive in the nineteenth century. Many new Christian groups emerged after the emigration of supporters of the government of Chian Kai-sheck to Taiwan from mainland China. The Jesuit missionary Francis Xavier introduced Christianity to Japan in 1549, after his initial mission to India who converted the Japanese court to Christianity. More than 300 000 Japanese followed their rulers and converted by the end of that century. However, Christianity was later proscribed, though small pockets of Christian activity remained. In the twentieth century Japan has been characterized by remarkable religious innovation, and many New Religious Movements have emerged, particularly since the Second World War. Parallel developments have occurred in Japanese Christianity. New indigenous styles of Christianity have emerged, and Pentecostal groups have also proliferated.

The Catholic Church has roots in Korea as far back as the sixteenth century but Protestantism has taken root in Korea in a manner it has nowhere else in Asia. Forty-one percent of the population are now Christian, and the majority belong to indigenous Korean and Protestant churches. The beginning of the twentieth century saw a particularly rapid influx of Koreans into the Protestant churches, and many Protestant churches have also experienced considerable growth since the Second World War. Seoul has some of the largest church buildings, and the largest congregations, anywhere in the world. Explanations for the strength of Protestantism in Korea are various. One theory is that there is a uniquely individualist strain to Korean Confucianism and that Protestantism individualism, with its more progressive conception of the role of the individual in the fast changing world of the twentieth century, proved particularly attractive to Koreans who were dissatisfied with Confucianism.

Southeast Asia

As a consequence of more than three centuries of settlement by the Spanish, and after the Spanish American war, by the United States, Christianity is the principal religion of the Philippines. Virtually the whole country was converted to Roman Catholicism under Spanish rule, though a Muslim minority remained, primarily in Mindanao. The Roman Catholic Church, however, was organized and run exclusively by foreign clergy and resentment at this resulted in an internal revolution whose outcome was the Philippine Independent Church which broke away from Catholicism after 1860. Protestant missionaries arrived with the Americans, including Episcopalians who set out to convert the mountain peoples in North Luzon as they had not been reached by the Catholics.

Roman Catholic missions were active in Vietnam, Cambodia, and Laos in the seventeenth and eighteenth centuries, and established churches in all three countries. Cambodia now has very few Christians indeed. After Year Zero Christians were totally purged from Cambodia. In Laos the Catholic Church has had most converts amongst tribal peoples on the border with Thailand but remains an insignificant presence elsewhere in the country. In Vietnam Christians, the great majority of whom are Catholic, constitute 7% of the population. The church was indigenized much more effectively in the North, whereas in the South local leadership was discouraged and there are far fewer adherents. Catholics have been close to political leadership in both North and South Vietnam and the Catholic Church in Rome and in Vietnam was a strong supporter of moves for peace during the war, and of subsequent North–South reconciliation efforts after the war.

Uniquely in Southeast Asia, Thailand has never been colonized by a foreign power and Thai Buddhism is particularly resistant to foreign, including Christian, influence. Strong Chinese communities in the large cities, and especially in Bangkok, are the main locus of Christian adherents. Myanmar Buddhists are also highly resistant to Christianity. Christians are most numerous amongst the Karen tribal group in the forests of the Northwest who are not Buddhist, and do not regard themselves as Burmese.

Christianity was introduced into the Indonesian archipelago by the Dutch in the sixteenth century. Christians are most numerous in Northern Sumatra where the non-Muslim Batak people converted to Christianity in large numbers. There are also

churches in most areas of Java, and on some of the other islands. Indonesian Christianity has been subject to the State religious doctrine of Panchasilla which requires that all religious groups express loyalty to the state and tolerance of other religions. Indonesian Christians were active in the struggle for independence from the Dutch after the Second World War and their partnership in the birth of the new independent nation may partly explain why, almost uniquely in the Muslim world, there have in the past been a number of religious conversions. However, a peaceful inter religious climate characterized by neighborliness and dialogue between the religions recently has turned to conflict as the Suharto and Habibi governments have stirred up religious conflict as a way of maintaining a hold on the votes of the predominantly Muslim population.

Christians in Malaysia number around 7% of the population, and 15% in Singapore. Dating back to the Portugese settlement of Malacca in the fifteenth century, Malaysian Christianity has taken up a range of influences including Portugese Catholic, Dutch Presbyterian, American Methodist, Anglican, and Pentecostal. Christians are confined to Chinese and Indian minorities on the whole, though tribal peoples in East Malaysia have converted to Christianity in large numbers. The fastest growing forms of Christianity in both Singapore and Malaysia today are Pentecostal or Charismatic. This modern style of Christianity has spawned many independent churches and has also been very influential in mainstream Catholic and Protestant congregations. Both countries have experienced a surge in religious interest and affiliation in recent years, sparked in part by Islamic resurgence among the Malays. This is reflected in a range of religious innovations both within Islam, Buddhism, and Hinduism, as well as in Christianity.

Christianity in Latin America

Abstract

In its Roman Catholic form, Christianity has been present in Latin America for about 500 years. During the colonial period, Christianity fulfilled a double role: that of validating the social order, beginning with the legitimization of the conquest itself, and also providing the justification for judging that same order. Religions' double function could also be seen at work among the indigenous population, for whom Christianity served as a vehicle of accommodation as well as protest. After independence, Latin American governments have generally regarded the Roman Church as an ideological ally, one which played a crucial role in the legitimization of the social order. But the privileged status of Catholicism has been challenged, first by the generalized, male anticlericalism typical of Catholic countries; then by positivism and the theology of liberation; and finally by the spread of Protestantism. After the breakup of Catholic hegemony and the rapid growth of evangelical churches there was growth and fragmentation; individualism but also the constitution of new communities; political quietism side by side with right wing activism. There are even churches that have reversed the traditional direction of missionary activity and have established branches outside Latin America.

Christianity has been present in Latin America for about 500 years. That period may seem brief if one compares it with almost two millennia of European Christianity, but the crusades that led to the Christianization of the Baltic countries did not end till the fourteenth century, less than two centuries before equally bellicose Christians arrived in the Western hemisphere. If one compares the present situation of Latin American and European Christianity, one finds that Latin America is in some ways more solidly Christian than Europe. The hegemony of Roman Catholicism is a thing of the past, and there is a low degree of religiosity in urban areas much as in Western Europe, especially in the Southern part of the hemisphere. Still, the religion that remains in Latin America, both public and private, is overwhelmingly Christian. The degree of religiosity may be weaker in the southern cone, urban groups everywhere may no longer engage in the ritual activities that were common just a few decades ago, and the influence of the Roman Church on the everyday life of Latin Americans may have diminished substantially, especially in matters regarding sexuality and reproduction; but contemporary Latin Americans are not likely to articulate political grievances in sectarian religious terms. It is true that the political power of conservative evangelicals has increased in recent decades, yet despite differences in terms of their social base, the evangelicals' attitudes to traditional sexual morality does not differ from that of conservative Catholic groups such as the Opus Dei. Oppressed, marginal, or disaffected groups may coalesce along social or ethnic lines (which tend to coincide in the region) forming violent gangs, but they are not likely to form gangs of Catholics or Evangelicals, which would parallel the Muslim youth groups in Western Europe; nor is society likely to suffer cleavages based on religious allegiances as is the case in the Middle East and South Asia. On the contrary, Latin Americans of, for example, East Asian descent, are as likely to be Christian or quasi-Christian, or no-longer-Christian as their fellow citizens. In what follows, we will examine the processes that led to the present situation.

Religion before the Conquest

As is generally the case in the preindustrial world – in which ideological claims are advanced in mythological terms and reinforced through ritual, especially sacrificial practices – in the area now known as Latin America, the social order was religiously legitimized. A proper discussion of the various ways in which this religious legitimization took place would require consideration of the range of societies found in Meso and South America, from kinship-based groups found in the Amazonian area, to chiefdoms, to states. It may suffice to say that societies organized as chiefdoms tend to be theocratic, their political life being heavily ritualized, and this form applies to early states, such as the Inca and the Aztec, in which the rulers were sacralized and considered the pivots of their society. Thus, in the Andean world the Inca dynasty, originally based in the area of Cuzco in Southeastern Peru, claimed descent from Inti, the Sun. In the Maya polities on the other hand, rulers engaged in elaborate ritual blood-letting to propitiate their gods.

More generally, religious legitimization meant that social distinctions, obligation to work, and access to resources were regarded as being regulated by an order that encompassed the social and the physical world. In order to preserve this order it was necessary to establish the links between this world and that of the gods through ritual, usually through sacrifice. Religion also structured time and space, as well as the relations between age groups and the sexes. The organization of time was accomplished at several levels: at the individual level this involved rites of passage, while at the macrosocial level the structuring required the use of liturgical calendars which were related to the seasons and, above all, to agricultural work. Similarly, space was structured by establishing mythological distinctions between neighborhoods and, at a more extended level, by dividing a territory by means of shrines along imaginary lines, an example of which is the *ceque* system centered in Cuzco, the Inca capital.

Conquest, Resistance, Accommodation

The fact that the political, religious, and economic spheres were less differentiated in the Aztec and Inca states than in sixteenth-century Western Europe may have contributed to the speed of the victory of the Spanish and Portuguese adventurers. The 'modernity' of the conquerors should not be exaggerated, since

 http://dx.doi.org/10.1016/B978-0-08-097086-8.84056-8

the processes that would lead to the scientific and cultural transformations of the seventeenth century took place mainly in Northern Europe, bypassing the Iberian Peninsula. Second, the Iberian discovery and conquest of America took place immediately after the defeat of the Muslim kingdom of Granada and the expulsion of the Jews who had refused to convert to Christianity, which means that the conquest itself took place as a kind of crusade at a time of Spanish politico-religious triumphalism. Moreover, attention should be paid to the fact that Columbus seems to have endowed his enterprise with a millenarian aura, hoping that a portion of the wealth found in the Indies would be used in the conquest of Jerusalem. This millenarian component can also be found at work in the self-understanding of some of the members of the religious orders involved in the process of conversion of the vanquished.

In any event, while the crusading spirit validated the conquest, the transcendentalization of religion and the concomitant separation between the roles of priests and those of soldiers and administrators, allowed some clerics to denounce the abuses of conquerors without, however, condemning the conquest itself. During the colonization of Latin America, therefore, Christianity fulfilled the double role traditionally accomplished by religion: that of validating or indeed sanctifying a social order, while also providing the transcendental justification for judging and condemning specific instances of abuse.

Religions' double function can also be seen at work among the indigenous population, for whom Christianity, which had been resisted at first – to the extent that many indigenous people killed themselves after witnessing the destruction their societies – eventually functioned as a vehicle of accommodation as well as of protest. The first aspect involved what is generally known as syncretism, that is, the amalgamation of Christianity and indigenous religions. Thus, in the Andes, the Christian god incorporated elements of Andean divinities such as Wirakocha and Pachacamac, while in Mexico Quetzalcoatl was assimilated into the apostle Thomas. The same identifications were made regarding goddesses: in Yucatan, Ixchel, the goddess of childbirth, was identified with the Virgin Mary; while in Mexico, the dark-skinned Virgin of Guadalupe, subsumed the Aztec goddess Tonantzin, 'Our Mother.' The fact that the physical appearance of Mary, – second only to Jesus in the Catholic pantheon – was said to resemble that of the Indian population rather than that of the conquerors, indicates on the one hand the extent to which at least part of the subjugated population had assimilated the new religion, and on the other, the intimate connection between religion and ethnic identification.

In some cases, conquered elites sought the protection of some of the most bellicose inhabitants of the Christian pantheon, expecting to profit from the power these supernatural beings had shown on the Spanish side; thus, the apostle Santiago, patron of Spain, became syncretized with the Andean Illapa (Lightning). And as early as the sixteenth century the Virgin of Copacabana was enlisted in the intradynastic struggles of native elites. Christianity also played a role in the indigenous rebellions against Spanish domination. This can be seen in the sixteenth-century Taki Onqoy movement, and more clearly in the late eighteenth-century Tupac Amaru rebellion, in which the rebels regarded themselves as better Christians than the Spaniards.

The adoption and mobilization of the symbolic resources of Christianity on the part of the conquered populations took place in informal and formal ways. The former involved the recognition that the supernatural resources of the conquerors were as effective as their military ones, leading to the adoption of both. In this context it was the ritual, especially the sacrificial emphasis of indigenous religions, that facilitated the recognition and then the assimilation of the ritual practices and sacrificial doctrines of Roman Catholicism. In fact, in the Mayan arena, in which sacrifice and self-sacrifice were practiced, Christian missionaries had to be careful with the display of images of the crucified Christ, for these encouraged actual crucifixions among the new Christians. The ritual appeal of the new religion was systematically reinforced by the labor of the missionaries, who carried out their tasks in different ways, seeking not just to gain new converts, but to advance the interests of their respective religious orders. In their effort to gain converts the Franciscans tended to pay little attention to doctrinal matters, preferring to baptize a large number of people in massive ceremonies, a practice that was criticized by the Dominicans and Augustinians, who proceeded in a more deliberate manner, emphasizing the doctrinal component of their task.

The systematic indoctrination of the new Christians was carried out differently according to their social position. Ordinary people would be introduced to the catechism and the rudiments of Christian doctrine through the sermons preached and the confessions heard by a small number of itinerant priests. These indoctrination efforts had to contend with the radical theological differences – whether the theologies were explicit or implicit – between Christians and non-Christians. Non-Christians did not have a conception of the personification of pure evil like the Christian devil, and they also lacked of belief in a unified soul. Even more important was the novelty of the Christian concern with belief and – notwithstanding the populous nature of the Christian pantheon – exclusive allegiance to one god. These theological presuppositions contrasted sharply with the ritual character of the indigenous religions as well as with the additive nature of the indigenous pantheons, which absorbed the gods of conquered peoples. To counteract these difficulties, the church concentrated its efforts on the male children of the conquered elites, who were subjected to systematic instruction in special institutions. Under normal circumstances such Christianization would have had a considerable impact on the population at large. The growth of Christianity was further spurred by the demographic collapses that occurred when plagues decimated the population that accompanied the conquest, which meant that the number of Christians increased as the population decreased, a process that parallels the spread of Christianity in the Mediterranean world more than a millennium earlier.

In addition to converting people to Christianity, the missionaries engaged in seeking the abolition of the old practices. This involved the physical destruction of shrines and temples, whose foundations or even walls served in some cases as the foundations of Christian churches (as can be seen to this day in the Church of Santo Domingo, built upon the Coricancha temple in Cuzco). No less important was the systematic destruction of religious documents and of mummies, which played a central ritual and political role in the Andean

world. The "extirpation of idolatries" campaigns, which lasted into the seventeenth century, in many cases achieved their goal by torturing people suspected of celebrating rituals centered around mummies. The most notorious was the burning alive in 1539 of the leader of Texcoco, Don Carlos Chichimecatecuhtli Ometochtzin, ordered by the 'Protector of the Indians,' the Franciscan Juan de Zumárraga. Another atrocity was the inquisitorial process carried out, once again by Franciscans, under the command of Diego de Landa in the Yucatecan town of Maní in 1562, which resulted in the torture and killing of several thousands of people.

Religion during the Colonial Period

The three centuries of Spanish and Portuguese control saw the continuation of the Christianization of the continent, a process that involved a great degree of ambiguity, as much among the indigenous groups as among the population of European origin. Among the former, the ritual system of Catholicism became part and parcel of everyday life, with sacrificial practices such as the offerings to the *pachamana* – the Andean mother earth – becoming integrated into Catholic rituals, and with the Catholic saints playing the role of the old divinities, much as it had happened in Europe centuries earlier. In rural areas, but even more in the cities, daily life was punctuated by the rituals of baroque Catholicism. At the individual and family level, there were the sacraments, which marked transitions in a person's life. At the level of the society at large, the rhythms of daily life were marked by religious ceremonies, whether these were processions, the public torture and executions organized by the Inquisition, or the solemn masses that celebrated the births and marriages of the royal families in the metropolis. For those of European descent the participation in the ritual life of the church was taken for granted, although in some cases such participation involved Jews who, despite prohibitions, had made their way to the New World pretending to be Christian. It must be remembered that regardless of religious allegiance, the relatively small number of people of European origin, the small size of the towns, the prevalence of gossip, and, not least, the vigilant attitude of the Inquisition, made nonparticipation in Catholic rituals risky. The same applied to the practice of blasphemy, which, widespread throughout the Christian world, had reached virtuosic levels in Spain and its colonies.

Ambivalence toward Catholicism was not unknown. That ambivalence gave place to hostility toward members of the clergy, on the rare occasions when clergy condemned the abuses heaped on indigenous peoples and African slaves. But the condemnations themselves were halfhearted insofar as the legitimacy of the colonial enterprise itself remained above critique. Likewise, despite the occasional clerical condemnation of the violence against slaves of African origin, priests had no difficulty finding numerous passages in the Old and New Testament that justified slavery. For instance, the seventeenth-century Jesuit António Vieira resorted to the Exodus story to show that "God does not complain about the Pharaoh, but rather about the overseers," meaning by this that whereas the abuses of the slave masters should be punished, the institution of slavery itself was divinely ordained. Important in terms of the intimate connection between theology and the social order was the fact that violence was regarded by Vieira and other priests as the ultimately negligible price that the slaves had to pay for the privilege of baptism, without which they were assured of eternal damnation.

The fear of damnation, this time on the part of the elites, led to the church becoming the beneficiary of donations, whose purpose it was to pay for the celebration of masses, which according to Catholic belief would shorten the time that the donor would spend in purgatory. These donations made the church the largest landowner in Spanish America, particularly in the cities, in which the churches, towering above the other buildings, punctuated space, just as the rituals choreographed time. As is the case in preindustrial societies, the theology, institutional weight, and the ritual apparatus of the militant Catholicism of the Counter Reformation, served to prop up the colonial system as one of the bastions of Spanish and Portuguese power during the three centuries of colonial rule. To maintain the Catholic monopoly – and to make sure that the colonies traded only with Spain – colonial authorities sought to protect Catholic orthodoxy from external threats such as Protestantism and the intellectual currents of the Enlightenment.

Religion in the New Republics

The role played by religion in the wars of independence of the early nineteenth century was contradictory. The lower clergy tended to side with those who wanted to achieve independence from Spain, whereas the higher clergy, many of whom had been born in the Iberian peninsula, were generally in favor of maintaining the colonial regime. For example, Miguel Hidalgo, the priest of Dolores who played an important role in the struggle for independence in Mexico, was executed in 1811 after the failure of the rebellion he instigated. On the other side, we find bishops such as the Spaniard Manuel Abad, who not only opposed independence for Mexico but excommunicated his former friend Hidalgo.

Once independence was achieved in the nineteenth century, the Creole elites kept in place the church's prerogatives, while at the same time seeking to control it by continuing the exercise of the right of patronage, just as the kings of Spain had done. In the case of legislation approved by the Congress of Colombia in 1824, this involved nominating bishops and archbishops, granting or refusing the publication of papal bulls and briefs, and enacting legislation to ensure the maintenance of the discipline of the church. After the governments of the new republics and the Vatican signed concordats regulating the status of the church, Roman Catholicism generally enjoyed a privileged position enshrined in the republics' constitutions. In the case of Ecuador, for instance, the concordat signed in 1862 recognized that the "Roman Catholic Apostolic Religion will continue to be the only religion of the Republic of Ecuador." Furthermore, Ecuador also recognized, unlike Colombia, the right of bishops to communicate freely with the Vatican and to make public papal documents without any government interference.

The situation was not always as favorable as clerical groups or proclerical governments would have wanted. As in Spain and elsewhere in the Catholic world, the hegemony of the Church contributed to an atmosphere of anticlericalism which

led to attempts to curtail the Church's privileges. This anticlerical attitude was intensified by the influence of liberal and positivist currents, which became widespread among intellectual elites in the nineteenth and early twentieth centuries. Anticlericalism was furthered by the realization by some intellectual and political elites that the Protestant United States had become a powerful country, while the new Catholic republics remained poor and backward. The most radical measures against Roman Catholicism were taken in Mexico, a country that reestablished relations with the Vatican only in 1992. In general, however, most Latin American governments have regarded the church as an ideological ally, one which played a crucial role in the legitimization of the social order.

Religion and Everyday Life

Catholicism has been an omnipresent reality in the life of Latin Americans, yet Catholicism has been lived differently by men and by women, by members of upper and lower classes, and in urban and rural milieus. As in southern Europe, in Latin America everyday religion in its private and public forms has been the domain of women, and, except for special occasions such as Lent and Christmas, women have constituted the majority of the faithful in Sunday services. But as an example of the ambivalence of popular attitudes towards religion in general and priests in particular, women who spent an inordinate amount of time in churches or hanging around priests were usually derided as *beatas*, (sanctimonious women), while men who did the same were mocked as *beatos*, and had their masculinity questioned. It is the mothers who traditionally have been in charge of introducing children to the rituals and the moral injunctions of Catholicism, more technical matters being left to priests. Social class also plays an important role in the process of religious socialization and children of the middle and upper classes are generally subject to religious indoctrination in schools directed by members of religious orders; whereas children of the lower classes, who attend state schools, are subject to minimal religious education.

One of the consequences of this religious indoctrination based on class distinctions is that Catholic revival movements such as Catholic Action, or political parties linked to Catholicism, such as Christian Democracy, involve mainly middle and upper class persons. In large cities, public religious activity is usually restricted to Sunday masses and to occasional processions, often including the participation of government dignitaries. The legitimizing role of Catholicism as the state religion can be seen at work in the solemn liturgies commemorating the independence days of independent South American States, and in the consecration of entire countries to Jesus or the Virgin Mary.

Popular Religion

The counterpart of official Catholicism is represented by what is known as 'popular religion' – those ritual practices that seem to elude and even oppose the control of religious elites. Ambivalence is at the core of popular religion, since in order to express opposition it is necessary to make use of the symbolic resources of the church. Popular religion is characterized by a complex system of assimilation and rejection, through which subordinate groups negotiate and struggle over access to cultural and material goods. Latin American popular religion comprises the syncretic processes referred to above, in which elements of the symbolic world of the Spanish conquerors were incorporated into that of the Andean, Mesoamerican and other conquered groups. It also comprises contemporary ritual practices in urban and rural milieus, such as processions and pilgrimages, which parallel the rituals choreographed by the official church and seek to establish – through religious fraternities (*cofradías*) – a measure of lay control over religious activities. Despite academic infatuation with symbolic resistance, the parodic and carnivalesque rituals of popular religion generally have not constituted serious threats to the hegemony of Catholicism or of the State. Along the same lines, it can be said that the expenditures required by the ritual calendar of indigenous communities may increase economic disparities instead of leveling them.

Millenarian Movements

Popular religious practices may lead to insurrections, particularly when the state attempt to suppress religious activities or charismatic leaders in a violent manner. This happened in Northeastern Brazil from 1893 to 1897, in the Millenarian movement of Canudos, and also in Southern Brazil from 1912 to 1916 in the Contestado rebellion. Both the Canudos and Contestado movements constituted reactions against the secular, positivistic values of the Brazilian republic – and in the case of the Contestado movement it is clear that the rebellion was triggered by the dislocations brought about by capitalism. Like Millenarian and Messianic movements in general, those that have taken place in Latin America have involved marginal regions in transitional periods and have been led by marginal, literate individuals, such as Antonio Conselheiro – the leader of Canudos – and Miguel Lucena Boaventura, known as José Maria, leader of Contestado.

Liberation Theology

At the elite level, the privileged status of Catholicism in Latin America has not gone unchallenged. In the nineteenth century, anticlerical groups influenced by positivism decried the Church's influence; and in the twentieth century, politically progressive groups opposed the alliance between oligarchic governments and the conservative church. During the early 1960s, prompted first by the triumph of the Cuban revolution and then by the Second Vatican Council, the traditional equation between church and conservative politics was broken. These events led some members of the Latin American clergy to question the role the church had played in the maintenance of an unjust social order. That questioning spurred the emergence of a 'prophetic' understanding of Christianity known as the Theology of Liberation. Liberation theologians were influenced by the social sciences as much as by traditional methods of theological exegesis and they removed concepts such as sin and salvation from the mere personal and spiritual realms to the structures of the societies within which sins were committed and salvation was sought. This theological approach – which

continues to be popular in progressive academic circles in the United States – was attacked by conservative Catholics, clerical and lay alike, who accused its proponents of forsaking Christianity and falling prey to Marxism. Despite its apparent threat to Catholicism, Liberation theology constituted an attempt to save Latin America's dominant religion by enlisting it in the task of reforming society. Liberation theology was ultimately attacked by the local churches and neutralized by Rome, and it gave up its distinctive use of sociological categories and retreated into traditional spirituality.

Alternatives to Catholicism

As the conflicts between Rome and the radical theologians were taking place, a far more important development was unfolding, namely the spread of evangelical Protestantism. There is a strong affinity between Liberation theology, which could be considered as a Protestant Catholicism, and the Evangelical churches. In both cases we find a Puritan faith centered upon the sacred texts and suspicious of the rituals of both official Catholicism as well as popular religion. Both Evangelical Protestantism and Liberation theology appear to be attempts to move away from a sacramental, hierarchical, agrarian-based vision of the world in response to the weakening of the agrarian economy and the ascendance of an urban world ruled by the market.

Instead of the 'disenchantment' of the world, to use Weber's term, we find two religiously ambiguous formations – the Evangelical and Catholic – whose task it is to mediate between the two worlds constituted by economic transactions and by the supernatural. In these two versions of Christianity there is still the attempt to preserve the presence of the transcendent, while at the same time deritualizing everyday activities. Deritualization has been explained in terms of the rationalization of economic activities, since it allows individuals and communities to avoid the burden of wasteful ritual expenditures and provides release from the pressures exercised by community and tradition. The result has been a world of ever-widening economic disparities, which must be confronted in an instrumental manner by the individual, rather than by the community. Rather than repressing emotion, individualism and instrumental reason seem to exacerbate it. Thus, as in the tense coexistence of Pietism and Enlightenment found in eighteenth-century Northern Europe, we find that the strongest forms of Latin American, non-Catholic Christianity are Pentecostal, and this has led to the emergence of charismatic forms of Catholicism – one more example of the proliferation of offerings in the religious market that emerged after the breakup of monopolistic Catholicism. Latin America has also seen the growth of New Age religions among the middle and upper classes, as well as of religions of African origin among groups which are not of African descent, even in countries, such as Argentina, which do not have a significant black population.

While the early spread of Protestantism was caused by the activities of North American missionaries, the subsequent growth of Evangelical churches is now largely fueled by local ferment. In some countries, such as Puerto Rico, El Salvador, Guatemala, Chile, and Brazil, Evangelicals constitute a significant proportion of the population; whereas in others, such as Venezuela and Colombia, that presence is much smaller. Considering the continuous growth of non-Catholic forms of Christianity, the equation between Latin American religion and Catholicism is a thing of the past. The Catholic Church can still exercise pressure upon governments and legislatures on matters related to the control of female sexuality, particularly on issues of abortion and access to birth control, yet the birth rate has decreased in the last several decades throughout the region. Despite the strenuous efforts of the Church, in 2012 abortion was made legal in Uruguay, as it is in Cuba, Guyana, Puerto Rico, and Mexico. In addition, while Chile, the Dominican Republic, El Salvador, Haiti, Honduras, Guatemala, and Surinam forbid abortions under all circumstances, the rest of the Latin American countries now have legislation that permits abortion to preserve the life or the health of the mother.

Conservative Trends in Catholicism

A development that is likely contribute to further loss of the popularity of the Catholic Church among the lower classes, while perhaps increasing it among high-income groups, is the growing importance of conservative Catholic groups such as the Opus Dei, a secretive organization supported by the Vatican, particularly during John Paul II's regime. But even in the case of the Opus Dei, one can see its promotion as an attempt on the part of the church to accommodate itself to a changing world. In effect, despite its authoritarianism and conservative views regarding sexual matters, the values promoted by this organization are consonant with the demands of an unfettered capitalist order and with modernity.

The election of the Argentinean Jorge Bergoglio as pope – the first time that a Latin American has been elected to that office – has caused a sudden increase in the popularity of the papacy, particularly in Latin America. Given the new pope's apparent concern for the poor and his critique of the reigning neoliberal economic orthodoxy, it can be expected that groups such as Opus Dei will lose the influence they once had in the Vatican. It remains to be seen if Pope Francis' popularity will result in an increase in the influence of the Roman Church in matters related to government policies or the everyday behavior of Latin Americans, especially in relation to sexual matters. It seems unlikely that the personal popularity of the Argentinean Pope will return Roman Catholicism to the hegemonic position it once had in Latin America.

Abstract

Canada, the United States, Australia, and New Zealand share origins as English colonies and thus are relatively young as nations and bound by Anglo legacies of language and culture. Protestant Christianity has functioned as a cultural establishment in each of these countries; Anglo religious life has been profoundly shaped by Protestant values such as resistance to religious authority, and a common experience and trajectory of religion and modernity in the West. While these countries are relatively young, their Protestant cultural establishments are increasingly viewed as old and faltering. Moreover, in the twentieth and twenty-first centuries, the historically dominant Protestant bodies in all these settings have suffered institutional declines and threats to cultural hegemony. There has been a notable rise in people identifying as having 'no religion,' but for many this entails more a separation from institutional religion than any divorce from the sacred. Spiritual eclecticism, drawing on Christian and non-Christian sources, as well as a focus on personal spiritual quest exist broadly inside and outside of Protestant institutions.

Historically, the major religious traditions for Anglo-America and Australasia are similar, despite the varying social and historical contexts in which they are located. That they all function, more or less, as cultural establishments within their countries provides a substantial basis for looking at them as a unified religious bloc. The countries making up this large bloc extending across continents – that is, Canada, the United States, Australia, and New Zealand – share origins as English colonies and, thus, are relatively young as nations and bound by Anglo legacies of language and culture. While the countries themselves are relatively young, in another sense the Protestant cultural establishments within them are increasingly viewed by many people as old and faltering – yet another reason for looking at them as of one piece. For all these reasons, comparative analysis of religious trends and dynamics is both possible and desirable, recognizing of course differences in size, polity, and demographics for the various countries.

Historical Considerations

From the outset, we should not underestimate the extent to which Anglo religious life continues to be fundamentally shaped by two historical realities: first, a Protestant background and thus a theological heritage of resistance to religious authority; and, second, a common experience and trajectory in the encounter of religion and modernity in the West. Obviously the two are closely related. The Protestant Reformation unleashed religious energies previously contained in medieval Catholicism and loosened the hold of ascriptive loyalties, thereby giving rise to greater autonomy of the individual in matters of faith and morals. Greater religious choice was accompanied by an elaboration of religious forms and styles, or a further working out generally of what is often referred to as the 'voluntary principle' within Protestantism. This principle is most pronounced in the United States, but elsewhere with Anglo influence, even in England itself, religious establishments have functioned in the modern period in an environment of considerable personal freedom. Protestantism has both given shape to, and been shaped by, high levels of individual freedom. In fact, three quite distinct historical waves of Protestant dissent legitimizing greater individual autonomy may be identified: first, the Calvinist movements; second, the Methodist revivals; and, more recently, the Pentecostals. As David Martin (1978) observes, the three religious waves correspond to shifting, ever-widening spheres of social influence. Unlike the Calvinists, who were limited mainly to social elites, the Methodists empowered working-class and middle-income populations, and the Pentecostals reached still lower social strata, and did so – and still do – in places and contexts often beyond the reach of the other two. For all three, the emphasis on the individual, on education and hard work, and on taking charge of one's life and making the most of it often resulted in upward mobility, and with that, a refocusing of belief systems and moral principles giving greater weight to the role of an individual's preference and conscience.

The encounter with modernity in the West led to a wide array of consequences, but most notably to a loosening of the binding character of tradition and memory (Hervieu-Léger, 2000) and an increased awareness of religious pluralism. Both mesh well with the mounting importance of individual autonomy and reliance upon personal choice in matters of belief. With this also came foundational shifts in faith, or what Peter Berger (1979) describes as a 'loss of ontological certainty.' Broadly speaking, the challenges to religious authority and increased pluralism ushered in an era of greater negotiation in matters of faith and commitment in the face of a widening array of choices. As the term 'secularization' is often used, it is much too encompassing and too easily glosses over the nuances of religion's encounter with modernity to adequately describe what happens in this situation, but it suffices to say that the latter as a historical and increasingly global process creates ruptures in shared religious views and forces upon ordinary people a posture of cognitive bargaining. Organized religion's monopoly over religious and spiritual questions is undermined. Religion's presence within the public arena takes on a new face. Philosopher Charles Taylor (2007, p. 3) describes 'a move from a society where belief in the traditional God is

largely unchallenged and unproblematic to one in which such belief is understood to be one option among others, and frequently not the easiest to embrace' – and yet the desire for spiritual 'fullness' and meaning persists. Growing numbers of people across Anglo-America and Australasia report having 'no religion' or being agnostics, yet many also simultaneously report being engaged in spiritual quests. From a Durkheimian perspective, religion and the sacred do not necessarily coincide, and indeed the emergence of the sacred as broader than or liberated from its earlier organized religious forms is a major transformation in our time.

For our purposes here, what is important are not just the parallels between Protestant influence and religion's encounter with the Enlightenment but also the fact that, as Berger and many other commentators point out, Protestantism has confronted the modern situation longer and to a greater extent than any other major faith tradition. That of course is rapidly changing in the contemporary world, where no religious tradition can insulate itself from pluralizing and individualizing trends. Yet for this very reason, the mainline Protestant experience is important and indeed paradigmatic of what other religions are now facing. Indeed, the fate of Protestantism in the modern West is what people of other faith traditions are quick to notice and worry about as perhaps their own. Apparent are deep internal strains within the tradition and disputes between liberal progressives, on the one hand, and conservative traditionalists, on the other, over moral and religious principles, brought about through selective interpretation of the tradition. In the case of the United States at present, we witness a strong and highly visible fusion of religious and political ideologies, an extension in ways yet also different from the earlier 'culture wars' of the 1980s and 1990s (see Hunter, 2010).

Yet it is not necessarily the case that 'Protestant' translates to 'Anglo' and certainly not that Anglo faith traditions can claim any superiority in their responses to modernity. The spiritual malaise that has currently fallen upon the historic, so-called mainline Protestant institutions throughout much of Anglo-America and Australasia augurs against any such claim. Nor is there any necessary presumption that other faith traditions must inevitably follow the Protestant trajectory in its confrontation with modernity; there are multiple passages and courses of accommodation. Even to argue that the Protestant experience, given its strong Anglo connections, is paradigmatic for other religious traditions is to risk the charge that this is still another, albeit subtle, claim to hegemony – alongside a broader history of racism, sexism, and capitalist exploitation. But there are widespread examples of 'Protestantization' within other faith traditions, such as the adoption of congregational forms of religious organization and the appeal to conscience relating to matters of faith and morality. Rather, we should look to the various countries described here as case studies in which to describe what is happening to these old Anglo religious establishments as they accommodate their peculiar social and cultural circumstances.

United States

The United States is the prime example of a country with a strong Protestant legacy, where the religious norms of individualism and adherence to conscience are now widely diffused and where the largely white, old-line Protestant denominations are mired in a deep spiritual malaise. Some would argue that the United States is the society that has undergone the greatest engagement with modernity, that in many respects its beliefs and practices are highly accommodated to its environment – religion in this context is secularized 'from within,' and thus a model of what to expect increasingly in the modernizing world. Yet, the United States remains highly religious among modern nations with regard to high levels of churchgoing and religious membership. This is true despite serious declines in membership within the old-line constituencies (notably the Episcopalians, Presbyterians, United Church of Christ, Disciples of Christ, and United Methodists) over the past 40 years, a time when the evangelical Christian sector has grown and become more mainstream. This overall switch in institutional forms is due to an array of factors: the influx of new-immigrant populations; higher birth rates and innovative programming, especially in the case of evangelicals; a more diverse Catholic population demographically and in terms of styles; generational changes favoring more direct, experiential faith communities; and, beginning with the Reagan presidency and lasting to the present, a reinvigorated conservative political ideology closely aligned with the social teachings of evangelical and fundamentalist Christian movements. Sometimes it is said that these old Anglo institutions have depleted their theological resources, that the problem is one of 'tired blood' in a context where there are so many fluid religious and spiritual styles.

The distinctiveness and vibrancy of religion in the United States are often explained by 'supply-side' and 'rational-choice' thinking, owing to a history of voluntarism and the necessity for religious constituencies to mobilize recruits as well as funds to sustain themselves. There is an emphasis on institutional innovation and competitive religious leadership. Carefully planned strategies in recruitment; the development of new types of religious organizations, such as megachurches; and the framing of religious messages for particular audiences coincide with a culture stressing choice as a principle across many sectors of life. That many Americans 'switch' religious affiliations as well as frequently move in and out of religious organizations underscores a high level of personal autonomy and decision making. With religion as with the mass marketing of goods and services generally, Americans respond to skillful packaging and presentation of the product. 'Selling God' and the working out of a principle of market differentiation in religion are almost as pervasive within the country as is the selling of anything else, although religious leaders resist the analogy.

A major shift, of course, is the increased religious diversity owing mostly to immigration as a result of the change in immigration policy in the mid-1960s. A major Pew Forum survey (2008) describes the breakdown of religious constituencies as follows: Christian, 78.4% (Evangelical Protestant, 26.3%; Catholic, 23.9%; Mainline Protestant, 18.1%; Historic Black Churches, 6.9%; Orthodox, 0.6%; and other Christians, 0.3%); Jewish, 1.7%; Mormon, 1.7%; Buddhist, 0.7%; Jehovah's Witnesses, 0.7%; Muslim, 0.6%; Hindu, 0.4%; other world religions, 0.3%; other faiths, 1.2%; plus unaffiliated, 16.1%; don't know, or refused, 0.8%; and a range of error of 0.6%. Those identifying as white Protestant

hover around or are less than 50% of the total population, a fact that has not gone unnoticed. Writing even some 40 years ago, sociologist Charles H. Anderson (1970, p. 3) observed, "The decline of the white Protestant majority and of white Protestant hegemony in twentieth century America has encouraged the growth of a self-conscious Protestant community." Such self-consciousness as well as anxieties relating to national identity are now considerably greater, especially among disadvantaged whites but also as articulated in some scholarly circles (see Huntington, 2005). Following 11 September 2001, the Muslim (and also Sikh) presence has evoked fears across many US communities of terrorism and of a changing American religious and cultural landscape.

A deep cleavage has emerged between religious traditionalists and religious progressives, one closely overlapping with political ideologies. The cleavage cuts across religious traditions but is particularly evident within the Christian sector. Since the 1980s, evangelicals and fundamentalists have picked up dropouts and dissidents from the more liberal Protestant churches, and the split within Catholicism along ideological lines has intensified. The thesis of a 'culture war' can be overstated since many Americans are caught in the middle on many social issues and are thus pulled one way or the other depending on the issue in question. Still, there is much tension and occasionally outright conflict, especially with regard to abortion and homosexuality. Disputes such as the latter arise out of seriously conflicting and often incommensurate notions of moral and religious truth and conflicting bases of authority from which to make such appeals: metaphorical as opposed to literalistic interpretations of scripture, and/or expansive, humanistic conceptions of the self versus a static view of human nature as in need of restraint.

Two other trends are important as well. One is the rise of a widespread spiritual quest culture that cuts across religious and nonreligious sectors. It flourishes among old-line Protestants who find their own rituals and worship services in need of rejuvenation; among 'seeker-minded' evangelicals who know very little about Christian tradition but are open to learning more; and among those who describe themselves as 'spiritual but not religious' or New Age spiritual, or simply adhere to a religio-spiritual system of belief and practice of their own choosing, often combining elements from various traditions (e.g., almost a quarter of Americans, many claiming to be Christian, report belief in reincarnation). The quest is for a greater sense of inner, experiential truth, to discover a more authentic and internally centered self (Roof, 1999). How this deepening of spirituality plays out in people's lives varies considerably. For many it takes the form of a personal journey, but for others it involves an enlivened sense of self within a supportive community. Words like 'soul' and 'spiritual,' which in an earlier time had all but disappeared in public discourse, have returned with renewed excitement. In this and other ways, the 'inward turn' today appears to be less a sign of protest against religion as such and more of assuming an effort to cultivate a meaningful sense of self and drawing upon of an array of resources to do so.

A second trend is the increase in numbers of people identifying with no religion, the so-called 'Nones'. In the 1960s, roughly 6% of people in the United States identified as having no religion; by 2012, that had climbed to 19 or 20%. The rise has been especially pronounced among young people, and among members of the millennial generation in particular roughly a third identify as nones (Pew Forum, 2012; Putnam and Campbell, 2010). Public intellectuals and organizations aligned with the 'New Atheism' movement, associated with the names of Richard Dawkins, Daniel Dennett, Sam Harris, and the late Christopher Hitchens, have been quick to claim this trend as evidence of increasing nonbelief. However, while atheist identification has expanded at a modest pace, atheists account for only a fraction of the no religion category; most report actually believing in God. Thus, while the upsurge of the nones and the elevation of 'spirituality' over 'religion' are troubling for many Protestant institutions, the persisting need for spiritual sustenance keeps the door open for religious innovation and perhaps even expansion. Christian movements such as the Emerging Church are taking advantage of this situation, yet it would be a mistake to assume the inexorable decline of traditional denominational forms.

Canada

Similar patterns of post-World War II Protestant decline are evident in Canada, despite the fact that the religious situation is very different there compared to the United States. Canada is historically less pluralistic (though that is now rapidly changing) and much more shaped by the presence of two large religious constituencies, Catholics and Protestants, vying with one another for power and influence. Catholics have long been numerous in Lower Canada, and Protestants, especially Anglicans, are sizable in Upper Canada. For the country as a whole, Protestants for a long time numbered more than Roman Catholics. But as of the 2001 census, Roman Catholics, benefiting from a higher birthrate and immigration streams, have become substantially larger with roughly 12.8 million members, concentrated particularly in Quebec. Protestants collectively number about 8.7 million, a 6% decline from 1991. The United Church of Christ (a merger in 1925 of Congregationalists, Methodists, and some Presbyterians) is the next largest at approximately 2.8 million members, concentrated in Ontario and the Prairies; the Anglicans claim roughly 2 million. Baptists were the only major Protestant group to increase significantly between 1991 and 2001, by 10% to about 729 000. Presbyterians, Lutherans, Pentecostals, and assorted conservative Protestant groups remain a significant presence, most below a million members. Presbyterians declined 36% between 1991 and 2001, the most of any Protestant group, and Pentecostals by 15%. Birth rates for Mormons, the Salvation Army, and conservative Protestant groups are generally higher than is the case for the more established Protestant denominations.

But the fate of Protestantism in Canada differs in some important respects compared with the United States. Mainline Protestants have suffered membership declines in Canada, losing both to Roman Catholic parishes and to some of the conservative churches. Proportionately they have lost more to Catholicism than is probably the case in the United States, where just the opposite pattern appears to be more prominent – that is, somewhat greater losses to the religious conservatives. Statistically, this is what one would expect: the larger the competing population, the greater the likelihood of mainline Protestants switching in as

a result of marriage or religious choice. The conservative religious presence in Canada is neither as well institutionalized nor as publicly visible as its neighbor to the south. Sociologist Reginald W. Bibby (2011, pp. 197–198) argues that in fact the alleged recent growth of conservative Protestantism in Canada is largely a misperception, more really a 'circulation of the saints,' or movement of people from one evangelical church to another, than a case of genuinely active and successful recruitment from other churches. Conservative Protestants tend to be converted over and over again – as a result of social and geographic mobility, marriage, divorce, friendship patterns, preferences for religious leaders, and congregational activities. Bibby's research suggests a slight increase in the recruitment of outsiders into the conservative fold over the past several decades, but even so the actual number of converts remains small.

Overall, levels of religious participation are moderate – higher than those of most European countries but lower than that found in the United States. Conservative Protestants have higher levels of weekly worship attendance than Roman Catholics and other Protestants, but because of their relatively small size proportionately and their tendency to circulate among themselves, their impact is not as widely felt as in the United States. In terms of inter-Protestant tensions, a liberal–conservative cleavage is evident, but the 'culture war' infrastructure in Canada is weaker than in the United States, and consequently it is less of a structural feature. The conservative-moralist flavor of evangelical Protestantism never held sway over Canadians in the way historically it did, and to some extent still does, in the United States. Sociologist Sam Reimer (2003) observes that while US and Canadian evangelicals in many ways resemble each other more than they do their fellow compatriots – for instance, in terms of emphasizing strong boundaries, the conversion experience, and similar styles of sexual morality – Canadian evangelicals are less religiously orthodox and less likely to align themselves with conservative politics, instead moving more fluidly across the political spectrum.

Particularly relevant to understanding the Protestant decline in Canada is the shift toward adopting 'no religion,' which parallels shifts in the United States and Australasia. In 1971, less than 1% of Canadians claimed 'no religion.' By 2001, however, such religious nones had increased to 16% of the population or 4.8 million people, usurping the Protestant position as the second largest 'religious' body in the country behind Roman Catholics. Young Canadians are especially likely to identify with no religion. While the ascent of no religion would seem on its surface to support secularization theories – and, as in the United States, Canadian proponents of the New Atheism are quick to claim the gains as their own – the data suggest a more complex picture. Bibby interprets the restructuring of Canadian religion as neither secularization nor religious revitalization, but rather as 'religious polarization' in which people increasingly move away from ambiguous relationships with religion and toward the entrenched embracing or rejecting of it. In 2005, roughly the same percentage of Canadians attended church weekly (25%) as did not attend church at all (23%). And yet in Canada, as elsewhere, even among the nones there does not seem to be a wholesale waning of spiritual need or quest. Research suggests that many of those identifying with 'no religion' not only seek out spiritual fulfillment but also are able to find it outside of conventional religion.

The wide-ranging constellation of individualized spiritual innovation and quest known as the New Spirituality is thus of great importance in Canada, and not just for spiritually inclined nones. The New Spirituality is less its own separate enclave than a general headwind moving through religious (and, it would seem, nonreligious) communities of all kinds, especially more moderate-to-liberal communities. In both the United States and Canada, many people interested in New Age, metaphysical, and mystical thought continue to identify with an inherited faith tradition – as Protestant or Roman Catholic. Religious as well as 'spiritual but not religious' Canadians often adopt pieces of outside philosophical and spiritual systems, combining them into a mélange that makes intuitive sense without feeling the need to shift their religious identification. It is not clear whether this dynamic is more the case in Canada or the United States, but in any case it represents a major convergence for the two countries in the adaptation of religion to modernity. In both of these highly individualized settings, religion is not so much abandoned in the strictest sense as it is privatized and modified to fit into people's life situations at any given time. Even where religion is overtly abandoned, as by the religious nones, relationships to the sacred often strongly persist.

Australasia

The very term 'Australasia' signals a confrontation and mixing of cultures, of East and West, a term quite fitting to both of our remaining countries, Australia and New Zealand. Both countries have a heritage of European settlement and Anglo dominance over aboriginal cultures, with the practices and structures of that heritage reflected in their social institutions. Both countries know the tensions arising out of an expanding religious pluralism, brought on largely by successive waves of new immigrants. Both are often described as increasingly secular societies, especially in political and civic life.

Yet there are significant differences. Australia has seen fewer new religions or even new versions of older religions than has New Zealand. Religious history for the former is more a telling of stories about a European past, unlike for the latter, where such stories are shaped more by local conditions and cultural and religious admixtures. Even Anglican Church history differs between the two countries. In Australia, the Anglican Church began as a convict church served by chaplains for whites, whereas in New Zealand, the Anglican Church was at first, and for a long time afterward, a Māori aboriginal church served by missionaries. It was not until the mid-1800s that the Pākehā, or white Anglicans, began to outnumber the Māoris. The Māori Rātana and Ringatū faiths are two examples of New Zealand's popular mixing of religious and cultural themes, combining aboriginal and Christian elements. This difference between the two countries need not be exaggerated, but it does register in religious and spiritual styles.

Australia's religious profile today is as follows: Roman Catholics, 25%; Anglicans, 17%; other (non-Christian) religions, 7%; and no religion, 22%. The Catholic ascendency over Anglicans emerged about 60 years ago. The old, well-established religious communities – the Anglicans, the Uniting Church, the Presbyterians and Reformed Churches, and the Lutherans – have all suffered declines during the past several

decades. Of these, the Anglicans fell most precipitously, declining 5% between 1996 and 2011. Christian or Christian-derived groups growing slowly or holding their ground include the Pentecostals, and the Jehovah's Witnesses. Non-Christian groups have expanded rapidly in recent decades due in large part to immigration, but remain proportionately small at less than 3% each. Of these, Hinduism saw the largest recent percentile gain, increasing by 86% between 2006 and 2011; Islam increased by 69%; and Buddhism by 48%.

The greatest change in Australian religious identification since World War II, and particularly among those born during this period, is the increase in people having 'no religion.' Religious nones presently stand at 22% of the population, concentrated especially among young people. Likewise, religious attendance has declined in most of the churches – and yet all the while, stated interest in spiritual well-being appears to have increased. Sociologist Gary Bouma (2006) argues that religion and spirituality are in fact flourishing in a 'postsecular' Australia, but in shifting forms often unhinged from traditional religious institutions and authority, and thus often overlooked by sociologists. This includes conservative evangelicalism and Pentecostalism, as well as New Age and nature spiritualties and boundless spiritual bricolage that draw creatively upon the diversifying religious and cultural landscape. Bouma (pp. 32–33) views Australian religion and spirituality as characterized by 'a shy hope in the heart,' as in temperament less brash and less prone to public display than is the case in the United States. There may actually be movement in the United States toward increased spiritual subtlety and quietude – the growing contingent of 'spiritual but not religious' people is often uneasy shoehorning their spirituality into words. But what seems clear is that Australia is host to a more dynamic spiritual and religious scene than is typically observed.

In New Zealand as of the 2006 census, the Anglicans remain the largest single constituency considering that both the Pākehā and the Māoris are included. Roman Catholics are the next largest population, followed by the Presbyterian, Congregational, and Reformed denomination, with a continuing strong Scottish heritage. About 40% of the population identify with one of the major Christian churches. Christian affiliations that increased between 2001 and 2006, while remaining a small percentage of the population, include Orthodox Christianity and evangelical and fundamentalist Christianity. Recent immigrant religious communities are growing rapidly through immigration but are infinitesimal in size compared with all others. There have been substantial declines in religious affiliation and congregational involvement since World War II, especially for major churches, and mostly as a result of trends among younger whites. Slightly more than a third of the population report having 'no religion,' and recent studies indicate rapid growth in this category. However, as throughout Anglo-America and Australasia, 'no religion' here seems to indicate discomfort with organized religious forms more than wholesale movement away from relationships with the sacred. One recent study found that as institutional religious adherence in New Zealand has declined, reports of religious experience have increased; and that 30% of the population agrees with the statement 'I don't follow a religion, but am a spiritual person interested in the sacred/supernatural' (Vaccarino et al., 2011). Spiritual forms on the ascent include New Age varieties and Anglo interest in Māori spirituality. The white and nonwhite populations are on somewhat different religious trajectories, evident most in the Anglo trends toward reduced organizational involvement. For the Māori, with their folk traditions and close spiritual attachments to the environment, organizational participation was never held up as a religious norm in quite the same way it was for Anglos.

Both Australia and New Zealand experienced enormous changes in the past half-century as they evolved from being made up predominately of villages and tribes to becoming more urban and multicultural in character. Religion, at least in its traditional organized forms, has lost much of its power to integrate life experiences and has become one among many life-worlds in which people may or may not participate. Anglo religious traditions have suffered in the process. There, as elsewhere in modern societies, we observe greater eclecticism and pragmatism. However, compared with Canada and even more so with the United States, two things stand out in making the religious responses to modernity in Australasia different: one is that fundamentalism seems to attract fewer people and offers less of a viable alternative, and the second is that there is less movement generally from one faith tradition to another, the more common movement being simply to leave organized religion in favor of 'no religion.'

Abstract

The present chapter considers the origins of Christianity in the first two centuries of its development, from the earliest Jesus movements to the writing of the apostolic tradition and institutionalization of the Roman Catholic Church. Departing from customary readings in biblical and religious studies whereby the study of Christian origins yields a singular and extraordinary event along the lines of an immaculate conception, whether literally or symbolically, the current line of inquiry presupposes a sociohistorical and cultural-anthropological perspective, noting that early Christianity is marked by the emergence of disparate and competing communities fighting for identity and social position.

Theoretical Considerations

At least since the appearance of Walter Bauer's (1934) publication, *Rechtgläubigkeit und Ketzerei im ältesten Christentum* (*Orthodoxy and Heresy in Earliest Christianity*), scholars have struggled with the fact that the early Christian texts testify not to a movement branching out into diverse and heretical representations of a singular event but to a discontinuity and difference that only later collapse into an emerging orthodoxy. The question is that if the essence of the movement is to be sought in the hour of its genesis, how is the traditional scholarship to respond when faced with a heterogeneous beginning? Unfortunately, rather than allow the disparity of origins to stand, and to refashion its philosophical sensibilities and methods in light of the human sciences, the scholarship insists that the emergence of Christianity must necessarily reflect a singular defining moment. Understood theoretically, whether the beginning is marked by an immaculate conception or simply by the extraordinary teachings of a Galilean Jew, all disparity is erased in favor of the lofty origin. Expressed historically, it follows the gospel narrative by charting a linear development beginning with the historical Jesus as the only point of origin, moving through the crucifixion and resurrection stories to the establishment of a church in Jerusalem, from which then proceed the missions of the apostles, first to the Jews (Peter) and then to the gentiles (Paul). A line of apostolic succession is then established whereby the core gospel is passed from the Apostles to the apostolic fathers, who in turn set in motion the founding of the Roman Catholic Church. Until recently, most constructions of Christian origins have fallen in line with this understanding, but the scholarship has seen a shift in thinking that takes seriously the plurality of its beginning as reflected in the diversity of texts, and makes full use of the theoretical perspectives of cultural anthropology and social theory (Castelli and Taussig, 1996; Cameron and Miller, 2004, 2011).

The Early Jesus Movements

Notwithstanding the overwhelming number of works that have sought to put forward a portrait of the historical Jesus, the most one can say is that he was a Jewish teacher from the region of Galilee who gathered together a small number of followers and whose teachings challenged local cultural conventions (Vaage, 1994). The nature of these early texts does not lend them to reconstructions of the life and personality of Jesus. On the contrary, the authors of these texts were not interested in preserving the historical person but in the appropriation of Jesus as founder and teacher of a school of thought addressing questions of cultural identity and social formation, questions that arise in response to Hellenistic assimilation, Roman occupation, competing Jewish communities, and the eventual destruction of the Jewish Temple in 70 CE.

Although it is clear that the earliest Jesus movements did not persist in the form in which they were conceived – not to mention the possibility that there could have been many other groups about which nothing is known simply because there is no documentation – there is little doubt that experimentation in social formation occurred early on, and that this process (somewhat disparate, to be sure) served as a foundation for the emergence of the later and more systematic attempts at social formation. Of these early Jesus groups, textual documentation for the following three is most in evidence: (1) the community that produced the Q document, (2) the community that produced the pre-Markan pronouncement stories, and (3) the community that produced the Gospel of Thomas. These texts represent a period of time somewhere between 40 CE and 60 CE. They precede the Gospels by several years, and do not reflect what will later become the Gospel story. They are, for the most part, collections of sayings that convey the teachings of Jesus; they contain neither birth narrative, nor passion narrative (trial and crucifixion), nor resurrection narrative.

Q is short for the German word *Quelle*, meaning 'source.' It is one of two source documents shared by the Gospels of Matthew and Luke (the other being the Gospel of Mark) and is the earliest extant record of a Jesus movement. Stratigraphic analyses of Q have demonstrated a community in the process of social formation, identifying the social context in accordance with the compositional history of Q (Kloppenborg, 1987; Mack, 1993). The formative layer consists of instructional material that represents a group of Jesus people associated with the lower administrative sector of cities and villages in the region of Galilee

who find themselves separated from the customary practices of the Temple and thereby respond by offering an alternative ethos. They call this ethos the kingdom of God, and it is characterized by a simple, almost cyniclike lifestyle. Subsequent layers of text incorporate prophetic and apocalyptic sayings that betray ever-increasing situations of conflict with representatives of the Temple system, including the Scribes and Pharisees. Fighting for position and identity, the Q community begins to imagine Jesus not only as its founder and teacher but also as a son of David, and to identify its members as the true sons of Israel.

Form-critical studies demonstrate that the Gospel of Mark appropriated a collection of stories customarily identified as pronouncement stories. These stories are structured formally as follows: Jesus is placed in a certain situation where someone challenges his teaching and/or activity. He then responds with a sharp answer that turns the tables on his challengers. For example, "When asked why they ate with unclean hands, Jesus replied, 'It is not what goes into a person, but what comes out that makes unclean'" (Mark 7:15). This collection of stories suggests a rather small rural community in conflict with local Pharisees regarding legal aspects of the Torah and the interpretation of purity codes. Unlike the Q community, there is no indication that the members of this group regarded Jesus as a son of David, or necessarily themselves as the true sons of Israel. Jesus is simply presented here as an extraordinary teacher who easily outmaneuvers the Pharisees and thus validates the group's daily practices (Mack, 1995).

In 1945, a collection of Coptic-Gnostic texts was discovered near the city of Nag Hammadi in Upper Egypt. Among these texts was a document with the title "These are the hidden sayings that the living Jesus spoke and Judas Thomas the Twin recorded," and signed at the end as "The Gospel of Thomas." As with the Q document and the collection of pronouncement stories, this text shows no interest in a biographical account of the historical Jesus, it consists almost entirely of sayings, and its focus is upon the teachings of Jesus. Unlike these texts, however, the Gospel of Thomas reflects a distinct trajectory of Jesus followers who embrace a Gnostic understanding of their founder and teacher. Jesus' teachings extend beyond the history of Israel; he is neither messiah nor son of David, nor the extraordinary rabbi who confounds the Pharisees. Rather, Jesus is the gnostic redeemer who awakens his followers to the nature of the cosmos and their place within it. As such, the Thomas community essentially rejects the epic of Israel and locates itself within a universe that transcends history and culture. Having received and understood Jesus' teachings correctly, they have become, like Jesus himself, the enlightened ones within whom the kingdom of God resides.

In addition to these three distinct groups of Jesus people, it is possible to identify at least two others, though the textual documentation is minimal. Like the community that produced the pronouncement stories, there appears to have been a community that produced a collection of miracle stories, which was also used as a source by the author of the Gospel of Mark. This group develops a series of miracle stories that play off of the exodus theme, identifying Jesus as a Moses-like figure who effects liberation not only from sickness and demon possession but also from poverty and oppression. Its social construct is not unlike the formation of Israel in Moses' time. Another group of Jesus people appears to have formed a small community in Jerusalem. Paul's letter to the Galatians, written in 55 CE, mentions two visits he made to the 'pillars' in Jerusalem, whom he identifies as Cephas (Peter), James, and John. The visits apparently dealt with a dispute over the teachings of Jesus with respect to the acceptance of gentiles into the community – most likely concerning the practice of circumcision – which suggests that the members of this group sought to maintain its Jewish tradition and thus held more firmly to the Jewish purity codes. Unfortunately, Paul says little else about these pillars and the community to which they belong, and there is no mention elsewhere of such a community. The names of Peter, James, and John do not reappear until much later, when they are cast in a bad light by the author of the Gospel of Mark shortly after 70 CE.

The Christ Cult and the Gospel According to Paul

The following declaration from Paul's letter to the Galatians reflects the emergence of a very different kind of Jesus movement outside the region of Palestine: "There is no longer Jew or Greek, there is no longer slave or free, there is no longer male and female, for all of you are one in Christ Jesus" (Gal. 3:28). Without question, the statement marks an extraordinary shift in thinking about social formation. To imagine a community wherein all traditional cultural boundaries are erased is, indeed, remarkable. And although one may surmise that the teachings of Jesus sparked a movement toward universality, the early Jesus groups did not betray as much. Moreover, the designation 'Christ Jesus' is here distinctive and no less remarkable. The early Jesus people in Galilee or Jerusalem would not have considered the Greek 'Christos' ('the anointed') an appropriate title for their teacher and founder. Although now attributed to Paul, the substance of the statement precedes Paul; he incorporated into his letters not only the ideas but also fragments of text (Rom. 3:24–26, 4:25; 1 Cor. 13:13, 15:3–5; Phil. 2:6–11) from a community ('the Christ Cult' as a descriptive designation) that emerged somewhere in northern Syria, perhaps in or around the city of Antioch, in the late 40s and early 50s (Mack, 1995). It is likely that some form of the Jesus movement(s) spread to the cities of Syria, Asia Minor, and Greece, where it attracted diaspora Jews as well as gentiles, and that the movement assimilated certain Hellenistic beliefs and practices, eventually emerging as a religious association along the lines of a mystery cult. And in keeping with common practice among the religious associations, the members may have gathered together for meals that became an occasion for storytelling and ritual, thereby constructing social identity. Drawing upon the Greek tradition of the 'noble death' and upon the stories of the Maccabean martyrs, the focus turns from Jesus as teacher to Jesus as noble warrior and martyr who, like Socrates, dies on behalf of his people, and like the Jewish martyr reemerges as a divine spiritual presence. Over time, Jesus the teacher is reimagined as Jesus the dying and rising Christ (the anointed son) who presides over the kingdom, the mystery of which is that all are invited to participate whether Jew or gentile, male or female, free or slave.

Though at one time a persecutor of the Jesus movements, Paul must have been convinced that the Christ Cult was on to something. Not only did he join, but also he became a leading figure in the movement. But in the beginning, as Paul's

correspondence with the Galatian and Corinthian groups reveals, not everything was to Paul's liking, nor was the Christ Cult free from the criticism of other Jesus movements (e.g., the pillars in Jerusalem). The dispute, of course, had everything to do with the all-inclusive nature of this community and the problems associated with this mixing of Hellenistic and Jewish sensibilities, especially as regards codes of table fellowship and the ritual mark of circumcision. Moreover, it would not have been easy for some of the Jesus people to make the transition from Jesus as the teacher and founder to Jesus Christ as the cosmic lord and savior of both Jew and gentile. But herein lies the genius of Paul's solution: if he could show that gentiles were also the children of Abraham, and thereby unite the Christ Cult with the history of Israel, then the ritual marks of ethnicity would not matter. All that is required is that one believed in Christ Jesus, who is now the fulfillment of the Torah. This is precisely what Paul did; and it is precisely this resignification of Israel's story that will help set the course for the emergence of Christianity as heir to the Hebrew epic, though it will be a matter of decades before the Pauline Gospel is fully entrenched and sanctioned by the writing of the apostolic tradition.

The Gospel Tradition

With the advent of the Roman–Jewish war (66–70 CE), everything changes. Not only is the city of Jerusalem and its temple destroyed, but also the entire history and significance of the Second Temple are put into question: the temple-state marked the center of Israel's epic, and it was to be the culmination of Israel's history as it came into full possession of the land and kingdom. But all that was now gone; the epic of Israel had to be imagined differently. The Scribes and Pharisees, forerunners to the rabbinic system, stepped in to fill the void: the written and oral traditions of the Torah were preserved and copied, the purity codes were maintained, and places of gathering (synagogues) had spread throughout the land. For the Jesus movements also, it was a matter of reimagining their place in this new world; they too were sons of Israel and, with the destruction of the Second Temple, had to reconsider their place as heirs to the kingdom. The solution came with a rereading of Israel's story wherein the coming of Jesus displaces the temple-state. It begins with the Gospel of Mark.

Written sometime in the early 70s, the Gospel of Mark is the first text to construct a life of Jesus – not a factual construction as imagined in contemporary biography, but a life narrative that enabled this northern Palestinian community of Jesus followers to establish its own identity and break free of the Pharisees and synagogues. Drawing upon the collection of pronouncement stories and miracle stories, as well as the Christ Cult image of a dying and rising god, the author of the Gospel of Mark writes the story of the son of God who is sent into this world to set right what the authorities of the Second Temple system had so clearly ruined. A new kingdom of God is imagined, and Jesus' death and resurrection mark the end of the temple and its sacrificial practices.

Several years later, the Gospel of Matthew (*c.* 88 CE) and the Gospel of Luke (*c.* 120 CE) will incorporate Mark's Gospel and weave it together with the Q document and material of their own making (the synoptic gospels). Jesus' life narrative will remain essentially the same, as will the displacement of the old (the Temple) with the new (the Passion narrative), but slight alterations, elaborations, and new material will reflect the distinct interests of their respective communities as well. The author of Matthew addresses a Jesus movement located in the region of southern Palestine, a movement that is troubled by the influx of gentiles and thus seeks to maintain a link with its Jewish heritage. Matthew's Jesus is tied genealogically to Abraham and David, he assimilates the role of rabbi and messiah, and his teachings (e.g., the Sermon on the Mount) serve to correct the teachings of his (their) Jewish counterparts. The Gospel of Luke, however, does not address the concerns of a specific Jesus group at all, but rather bears the form of a history intended to reach a much larger gentile audience in a much later period of time. Looking back on the last 50 years, the author constructs a history of salvation that begins with Adam, runs through the history of Israel, manifests itself in the passion narrative, and moves out to the nations of the world. The brilliance of this composition lies in a reconceptualization of an apostolic tradition that links the mission to the nations with the Jesus of the Gospel tradition.

The fourth Gospel (later attributed to John the beloved disciple) makes its appearance in the years between the Gospels of Matthew and Luke, sometime around 95 CE, and reflects a Christian community that developed its own distinct view of Jesus and what it meant to be a member of this community. It is difficult to trace the origins and evolution of this social formation. Nevertheless, textual elements suggest a Jesus group that emerged in the mid- to late 40s somewhere near Syria that, as with other Jesus groups, contended with local Jewish authorities regarding the observance of purity codes. Over time, the community developed a Christology (Gnostic in tenor) that presented Jesus as the divine Logos become flesh and constructed a narrative that reflected its severed ties with its Jewish family entirely: members of the Johannine community were encouraged to leave the synagogues and look upon 'the Jews' (no longer simply Pharisees) as those who failed to heed the signs and acknowledge Jesus as the way, truth, and light – the community of darkness.

Writing the Apostolic Tradition

With the exception of the Pauline letters, very little documentation exists that provides information regarding the early history of the apostles – in fact, the term itself must be used carefully when considering its early history. Aside from those limited references noting Paul's conflict with the pillars in Jerusalem, and apparent opposition to Paul's claim of apostleship (both referencing disputes over ethnic boundaries), all that can be said with any certainty is that the turn of the first century CE marked a distinct shift from Jewish Christian communities to predominately gentile Christian communities – which is not to say, however, that the respective communities were without their own internal disputes. When turning to Luke's Acts of the Apostles, the frequently made mistake is to assume that the book is a descriptive text, a factual record of what actually happened. But this is not the case. The apostles have been dead for many years, and the history that Luke writes comes after the fact. In broad strokes, the book charts out the course from Peter's mission to the Jews to Paul's mission to the gentiles, culminating with Paul's arrival in Rome. What proves so

remarkable about the writing of this tradition is that it sets the foundation for an apostolic succession of inheritance that will authorize the teachings and practices of the Church of Rome. Of course, there never actually was a line of succession that preserved an original orthodoxy. No scholar today believes that the disciples of Jesus, the so-called 12 apostles, passed along a core gospel to the apostolic fathers, who then set in motion the founding of the Roman Catholic Church. Nevertheless, Luke's Acts of the Apostles will come to serve as a myth of origins authorizing the apostolic line of succession, a simple yet successfully imagined history that will come to pass: the Jesus of the gospel tradition invests the apostles, the apostles invest the apostolic fathers, and the apostolic fathers will lay the foundation for the formation of the Roman Catholic Church.

The Path to Orthodoxy

Several years of conflict and resolution lie ahead before Luke's vision of the apostolic tradition is realized. Diversity will persist well into the second century. Numerous gospels, acts, epistles, apologies, and treatises will be written during this period of time, conveying diverse beliefs and practices represented by several Christian communities scattered throughout Syria, Palestine, and North Africa: Judaizers, Hellenists, Gnostics, aesthetics, women-specific communities, and more. Later, with the formation of the New Testament canon, many of these writings will comprise the collection of hidden texts (or Apocrypha) and the Gnostic writings of the Nag Hammadi library. In the midst of this diversity, the Christians who settled in Rome began to organize and develop an episcopate. The central players in this process, those who would later become known as the *apostolic fathers* (a seventeenth-century designation of orthodox scholarship), left a collection of writings that signaled movement toward a desired ecclesiastical organization of the episcopate seated in Rome, as well as a consolidation of early Christian writings and the belief that Christianity is the culmination of Israel's epic: letters attributed to Clement of Rome, letters of Ignatius of Antioch, the Didache, a letter attributed to Barnabas, an apocalyptic text entitled the Shepherd of Hermes, the Martyrdom of Polycarp, and the Epistle to Diogentus. Despite their efforts, however, the fathers were unable to secure a united front whereby their understanding of Christianity as the orthodox transmission of the gospel could be firmly set against so-called heretical manifestations. The turning point occurs in the middle of the second century (*c.* 140–150 CE), when the legitimacy of the episcopate in Rome is directly threatened by the growing popularity of two distinct visions of Christianity: the anti-Jewish vision of Marcion of Sinope and the Gnostic Christian vision of Valentinus of Alexandria.

Marcion drew immediate attention with the introduction of the first 'New Testament' canon, the intent of which was to sever all ties with Judaism. He believed that the God of Israel was the creator of a malevolent world, and that such a deity could not possibly be the God who sent Jesus, the merciful son, into this world. Christianity had already freed itself from the Mosaic law, and so it did not make sense to Marcion that Christians should maintain this connection with the God of Israel. Hence, he rejected the Jewish scriptures and all early Christian writings that retained a connection with Judaism, and proceeded to produce a canon of literature consisting of 10 Pauline letters and a truncated version of the Gospel of Luke. Valentinus, who laid claim to apostolic authority, was a leading figure in the Gnostic Christian movement of Alexandria, a movement that likely had its precursor in the early Jesus group that produced the Gospel of Thomas. The vision of Christ is that of the Gnostic redeemer through whom knowledge (gnosis) of the way back to the divine realm is imparted to those destined to return. They are the enlightened ones who move within a universe that transcends history and culture. The epic of Israel becomes irrelevant, and those who would lay claim to it remain ignorant of the knowledge held by Valentinus and the Gnostic Christians.

For the Church in Rome, the link with Judaism was foundational. The history of salvation, the plan set by the God of Israel, was marked by the coming of Christ, the legacy of which was entrusted to the Apostles who passed it along to the fathers and bishops in Rome. The response to Marcion and Valentinus came swiftly, first with the arguments set forth by Justin (Martyr) of Samaria, and then later supported by the writings of Irenaeus, Clement of Alexandria, and Tertullian. These were all highly educated men who presented powerful arguments demonstrating that the God of Israel was the Christian God who created the world, and that the line of succession leading to the Church in Rome was the divine plan from the beginning. Perhaps more importantly, however, these new Christian intellectuals also made the case to the Romans that Christianity as a religion was good for society and the government of Rome (Mack, 1995).

The conflicts would continue for some time to come, but the path to orthodoxy was clearly set, and the fathers in Rome would eventually win the day. Seven decades later, Constantine would convert to Christianity (313 CE) and shortly thereafter become emperor of the Roman Empire in 324 CE. In 325 CE, he called the first council of bishops to meet in Nicea and charged Eusebius, bishop of Caesarea, to collect the sacred scriptures and produce 50 copies for distribution among the new churches in Constantinople. Thus begins the formation of the New Testament canon and the centralization of Christianity in the Roman Catholic Church.

Chronic Illness, Psychosocial Coping with

Linda D Cameron and Christopher M Wally, Psychological Sciences, University of California-Merced, Merced, CA, USA

Abstract

Chronic illnesses are the leading cause of mortality worldwide. Generally noncurable, they range in severity from mild to life-threatening. Coping with the diagnosis and management of a chronic illness can be challenging for individuals and close others. Coping methods include problem-focused coping, emotion-focused coping, disengagement, accommodative coping, meaning-focused coping, and relationship-focused coping. How one copes may depend on individual differences such as emotional suppression tendencies, monitoring or blunting of information, and illness beliefs. Poor coping may worsen physical health through chronically elevated distress. Coping skills interventions can facilitate adaptive coping for individuals with chronic illness and their partners and families.

Chronic Illness and Coping Behaviors

Chronic illness is a long-lasting and permanent illness that is not curable by treatments and does not resolve over time. Chronic illnesses are the leading cause of mortality, accounting for an estimated 60% of all deaths worldwide (World Health Organization, 2011). They are highly prevalent in most developed countries. In the United States, for example, over 50% of the population has a chronic condition at any given time. Chronic illnesses range in severity from mild or moderately serious disorders, such as mild and well-controlled asthma, to serious and life-threatening conditions such as diabetes, heart disease, and cancer.

Most individuals diagnosed with a chronic illness experience at least some adverse consequences, threats, and limitations that have the potential to reduce their quality of life. Individuals use a variety of coping behaviors or strategies for managing the consequences brought on by their chronic conditions. Coping behaviors are defined as the efforts taken by an individual to manage threats, challenges and harms, or to manage the emotional distress they create. Understanding how individuals cope with chronic illnesses and the conditions under which specific coping strategies can be adaptive or maladaptive is a key area of research in social and behavioral sciences within the health field, including behavioral medicine, health psychology, nursing, public health, medical anthropology, and medical sociology.

Experiences Requiring Coping Efforts

For individuals diagnosed with a chronic illness, a primary coping goal is to manage or control disease progression through use of medications and other medical treatments as well as through diet, physical activity, and other health behaviors. Yet chronic illnesses also require coping with other aspects of the illness experiences. For many individuals, the development and diagnosis of a chronic illness is a disruptive and life-changing experience requiring significant changes in at least some areas of life. Aspects of life affected by chronic illness include somatic experiences, functional abilities, lifestyles, daily activities, social roles, self-concept, expectations for the future, and goals and priorities.

Individuals face challenges in enduring significant pain and noxious symptoms caused by the chronic condition and its treatment. For example, individuals with migraines suffer excruciating headaches that can last for several days; moreover, their unpredictability of occurrence can further undermine work progress, social plans, and psychological well-being. As another example, individuals diagnosed with colorectal cancer undergo painful treatments such as bowel surgery, chemotherapy, and radiation therapy. Chronic illnesses can cause other symptoms such as dizziness, itchiness, numbness, and lack of muscle control, all of which can cause discomfort and interfere with daily activities.

Chronic illnesses and their treatment can also lead to detrimental changes in cognitive and emotional function. Alzheimer's disease, Parkinson's disease, and brain cancer are just a few examples of chronic illnesses involving deterioration in cognitive functions. Individuals undergoing chemotherapy for cancer often experience cognitive deficits, and medications for numerous chronic conditions carry side effects such as depressive mood, confusion, and nervousness. The physical, somatic, and cognitive consequences of chronic illness can substantially limit abilities to engage in daily life activities such as running errands, socializing, working, and caring for others.

Chronic illness typically creates some degree of psychological distress. Anxiety is common, especially when waiting for test results, undergoing invasive medical procedures, and considering prospects of disability or death. For example, individuals treated for cancer report that fears of recurrence and spread are their top concern (Simard et al., 2013). Depression is also common among individuals with chronic illness, with greater illness severity being associated with higher levels of depression.

Key factors contributing to anxiety and depression include challenges to one's self-identity or self-concept, defined as the set of beliefs about one's qualities and characteristics, and self-esteem, defined as one's sense of self-worth. The physical and mental consequences of a chronic illness can lead to detrimental changes in body image, views of one's capacity for achievements and social activities, and ambitions and goals for the future. Chronic illnesses can also lead to real or perceived

stigma from others (Lee et al., 2002; Chapple et al., 2004). For example, individuals who experienced a stroke, smokers diagnosed with lung cancer, and individuals with HIV or AIDS frequently report instances in which they felt that others avoided contact with them, blamed them for their conditions, or acted toward them in a discriminatory manner.

Chronic illnesses significantly affect spouses, partners, and other family members, particularly those who serve as caregivers. These individuals must also engage in coping behaviors to manage the consequences, threats, and distress created by the illness and caregiving experiences. Individuals with a chronic illness and their spouses or partners often engage in dyadic coping, in which they view the illness as a shared experience and engage in joint coping efforts (Bodenmann, 2005). Dyadic coping may be positive when partners coordinate their efforts and express solidarity and togetherness in managing the illness-related challenges and tasks facing them. Alternatively, dyadic coping can be unbalanced or negative when one or both partners are combative, avoid or withdraw from stressful situations, are unresponsive to attempts to provide empathy or assistance, or fail to reciprocate provisions of support.

Distinctions in Coping Behaviors

Coping behaviors have been characterized in a variety of ways in social, behavioral, and health sciences. Different theoretical models of coping identify distinctions that have been used to guide empirical research and the development of coping measures. In this section, we review some of the more common distinctions used in research on coping with chronic illness.

Problem-Focused and Emotion-Focused Coping

A primary distinction in coping behaviors is between problem-focused and emotion-focused coping efforts (Carver et al., 1989; Lazarus and Folkman, 1984; Leventhal et al., 2012). Problem-focused coping behaviors are those aimed at reducing or resolving specific threats or negative consequences, such as controlling symptoms or finding ways to overcome illness-related barriers to engaging in work tasks. Emotion-focused coping involves the management or regulation of emotional distress caused by illness experiences, such as managing fears about treatment through expressing one's feelings to a spouse or seeking reassurance from a doctor. Common types of emotion coping strategies include expression or suppression of one's emotions with others, cognitive reframing or positive reappraisal of situations (e.g., focusing on one's ability to control one's diabetes through one's diet and physical activity), focus on negative thoughts (e.g., rumination about the illness threats and consequences), avoidance of negative thoughts (e.g., blocking out negative thoughts), avoidance of distressing situations (e.g., delaying or canceling routine health care visits for one's diabetes condition), and modulation of emotional states through the use of relaxation, alcohol or other substance use, or immersion in pleasurable activities.

Individuals often engage in both problem-focused and emotion-focused coping in order to meet the dual goals of controlling the objective threats and consequences created by the illness condition and managing emotional distress. Problem-focused and emotion-focused coping can be enacted in parallel or at different times during the course of illness. Moreover, they tend to interact and affect each other; for example, effective problem-focused coping can decrease emotional distress, thereby reducing the need for emotion-focused coping. Both types of coping behaviors can be helpful or detrimental, depending on the situation and how it is used. Problem-focused coping can be adaptive when a problem is solvable, but potentially maladaptive, if the threat or problem is uncontrollable. For example, an individual with advanced illness may find that persisting with a search for treatments that will cure the disease results in fruitless searching and ongoing frustration. Similarly, emotion-focused coping can be adaptive when it reduces distress, but it can be maladaptive if it interferes with active coping with the illness or leads to unhealthy behaviors.

Coping Engagement and Disengagement

Researchers also make a distinction between engagement and disengagement in coping efforts. Engagement refers to efforts to actively change or resolve problems or emotional distress, whereas disengagement refers to avoiding or ignoring the problematic issues or blocking out the distressing emotions. Disengagement generally involves those emotion-focused coping efforts aimed at escaping from emotional distress such as through avoidance, distraction, denial, and use of mind-altering substances. Disengagement from coping with a chronic illness is commonly unsuccessful over the longer term, and it can lead to dangerous outcomes even in the short term. For example, individuals with diabetes who ignore their condition and fail to eat meals when needed put themselves at risk of severe hypoglycemia, which can lead to mental confusion, unconsciousness, and seizures. Similarly, individuals with asthma who are in denial about their chronic health condition may fail to take their asthma prevention medication and thus increase their risk of serious and potentially fatal asthma attacks.

Disengagement from coping with illness-related problems does not always lead to maladaptive outcomes. In some instances, individuals may find that their quality of life improves when they let go of or give up on a goal. For example, individuals with end-stage cancer may decide to discontinue highly aggressive chemotherapy treatments that have little chance of slowing the progress of the cancer so as to preserve the quality of their final phase of life. As another example, athletes who are diagnosed with a life-threatening heart condition may choose to discontinue their sport as a health-protective measure. Importantly, however, these athletes are likely to cope best if they find a way to replace this important goal pursuit with an equally satisfying goal pursuit, such as an alternative profession that is just as rewarding or a role as a coach in the sport (Scheier and Carver, 2003).

Accommodative Coping and Meaning-Focused Coping

Another perspective that has guided research on coping with chronic illness gives emphasis to forms of engagement coping

involving efforts to adjust or adapt to the chronic illness. This form of coping, termed accommodative coping (Skinner et al., 2003), refers to cognitive adjustments in how one views the illness and the self as a means of coming to terms with unavoidable constraints arising as a consequence of the illness. Emphasis is given to coping strategies such as acceptance and changes in life goals and expectations; cognitive restructuring or reframing to minimize the costs and maximize the benefits of illness experiences; and distraction through engagement in positive activities such as hobbies, volunteering, family roles, and work projects.

Considerable research has focused on specific forms of cognitive restructuring known as meaning-focused coping. Meaning-focused coping refers to efforts to identify benefits and positive outcomes arising from the illness experience. For example, individuals with chronic illnesses often report that the experience has brought one's family closer together, made them stronger, served as a catalyst for positive experiences, and enabled them to understand what is truly important in life (Pakenham, 2011). Meaning-making and benefit-finding tend to increase with increasing severity of the illness condition, suggesting that individuals are increasingly motivated to utilize these coping strategies when illness consequences are regarded as relatively uncontrollable and improvement is unlikely. Evidence on outcomes of benefit-finding is mixed: Use of benefit-finding generally predicts lower depression and more positive affect over time, but it has been found to predict deleterious quality-of-life outcomes for some groups, such as those with more severe disease (Tomich and Helgeson, 2004).

Relationship-Focused Coping

In addition to the coping methods used to personally manage a chronic illness, individuals with chronic illness also utilize coping strategies to maintain their intimate relationships. Relationship-focused coping refers to efforts to preserve the quality of interactions and exchanges of social support with their partners. Active engagement coping, a common strategy involving the use of problem-focused efforts to resolve relationship conflicts brought on by the illness, tends to be beneficial in promoting well-being and marital satisfaction for both partners (Hagedoorn et al., 2000). Also beneficial to psychological adjustment and marital satisfaction among partners is communication about the relationship and the challenges brought on by the illness, as well as empathic responding to the partner's concerns (Acitelli and Badr, 2005; Bodenmann and Shantinath, 2004). Another coping strategy, protective buffering, has shown mixed results. Attempting to protect a partner from distress by masking one's own feelings may reduce distress for the partner, but it may increase distress for the partner who is suppressing emotions.

Individual Differences in Styles of Coping

Although many situational factors influence the selection and use of coping strategies over the course of a chronic illness, stable personal factors also shape these coping behaviors. Individual differences in coping include stable preferences for specific styles of coping, such as emotional suppression tendencies and information seeking styles characterized by either monitoring for or blunting out threat-related information. Individual differences in beliefs or cognitive representations of the nature of the illness also lead to differences in coping behaviors.

Emotional Suppression Tendencies

Suppression of negative emotions is a common emotion regulation tendency. Also known as emotional control, it is defined as a stable tendency to consciously inhibit expressive behaviors (including verbal, facial, and other nonverbal behaviors) reflecting negative emotions such as fear, anxiety, anger, frustration, sadness, and depression. Early research on how individuals cope with cancer revealed that patients commonly reported attempts to 'put on a brave face' and hide their negative emotions from others (Watson et al., 1991; Temoshok and Dreher, 1992).

Although suppression can carry short-term benefits in impression management and protecting others from one's personal distress, it tends to sustain negative emotional arousal, increase sympathetic activation, exacerbate symptoms, and interfere with successful coping. For example, a study of women undergoing chemotherapy for breast cancer treatment revealed that emotional suppression tendencies (particularly anger suppression) predicted higher levels of symptoms relating to immune function and cardiovascular arousal, as well as appraisals of poorer coping with the treatment (Schlatter and Cameron, 2010). Emotional suppression over the longer term can lead to detrimental health outcomes, including poor control of heart diseases and cancers, at least in part through the heightened physiological reactivity generated by sustained emotional distress. For example, correlational research links emotional suppression tendencies with poor adjustment to cancer experiences as well as faster cancer progression (Watson et al., 1991; Weihs et al., 2008).

Monitoring and Blunting Coping Styles

Monitoring and blunting coping styles can influence coping efforts related to information seeking, symptom monitoring, and use of medical treatments. Individuals with a monitoring coping style are motivated to scan for, attend to, and amplify information about their illness and potential treatments, whereas individuals with a blunting style are motivated to avoid and block out such information. High monitors benefit from opportunities to receive detailed information about their illness and treatment procedures, and they are likely to engage in careful monitoring of somatic experiences. For example, women in childbirth who were high monitors benefited from viewing a contraction monitor (Shiloh et al., 1998). High monitors tend to be more knowledgeable about their conditions in relation to low monitors, but they tend to be less satisfied with information provided by health sources, hold more negative beliefs about their condition, and experience more emotional distress (Roussi and Miller, 2014). High blunters tend to compartmentalize their illness from other areas of their lives and generally feel better when not attending

to threatening information about their illness. They tend to benefit from activities that enable them to distract their attention from noxious illness experiences, such as relaxation techniques prior to surgery (Miro and Raich, 1999).

Illness Beliefs

Subjective beliefs about the nature of one's illness influence the selection and enactment of coping strategies. According to Leventhal's Common-Sense Model of Illness Self-Regulation (Leventhal et al., 2012), individuals develop cognitive schema or representations of their illnesses based on past illness experiences and information from health care professionals, the media, and social networks. These representations guide efforts to cope with the illness itself and they generate emotional responses that trigger emotion-focused coping efforts. The Common-Sense Model identifies five primary attributes of illness representations: identity (beliefs about the illness label and associated symptoms), timeline (beliefs about its chronicity and episodic patterns), cause, consequences, and controllability/curability. Each of these beliefs can influence coping efforts (Hagger and Orbell, 2003). For example, individuals with hypertension, an asymptomatic disease, often erroneously identify symptoms that they believe arise when their blood pressure is high and they take their hypertension medication only when those symptoms are present (Meyer et al., 1985). Beliefs that an illness will have catastrophic effects can inhibit problem-focused coping and trigger emotion-focused coping efforts. Beliefs that an illness is acute rather than chronic in nature can lead to cessation of medications once symptoms seem under control.

Health Effects of Coping with Chronic Illness

Coping efforts can affect physical health through two routes. First, engagement in problem-focused strategies to control the illness through treatment adherence, healthy behaviors, symptom monitoring, and use of health care services can facilitate disease control, slow rates of disease progression, and promote social and physical functioning. Second, coping efforts that reduce emotional distress can inhibit physiological distress processes that can exacerbate disease progression. Threat-induced emotional distress activates the body's *flight or fight* response system, which includes activation of the hypothalamic-pituitary-adrenal (HPA) system and the sympathetic-adrenal-medulla (SAM) system. These systems prepare the body to respond to threatening situations by taking actions such as engaging in combat or fleeing from danger. Although adaptive in the short term, prolonged activation of the SAM and HPA systems can lead to detrimental physiological states. Prolonged SAM activation can exacerbate elevations in blood pressure, heart arrhythmias, and sleep difficulties; and prolonged HPA activation can promote inflammation and impair immune function (McEwen, 2004). Through these physiological processes, emotional distress could contribute to chronic illness episodes such as flare-ups of eczema, asthma attacks, and cardiac events; and it could accelerate the progression of immune-related diseases such as cancers and inhibit the healing of wounds from surgery and other procedures (Byrne-Davis and Vedhara, 2008; DeSteno et al., 2013). Problem-focused behaviors that reduce or resolve negative consequences of a chronic illness and emotion-focused behaviors that foster adaptive emotion regulation can not only promote mental well-being, but can also promote physical well-being and disease control.

Interventions to Improve Coping with Chronic Illness

Research on how individuals and their families cope with chronic illness has guided the development of interventions designed to improve their coping skills. These interventions typically target multiple coping skills such as problem-solving, communication, health behaviors, emotion regulation, and cognitive restructuring. Interventions can involve either group-based or individual sessions, and internet-based coping skills interventions are becoming increasingly common. Primary goals of these interventions include improvements in adherence to treatments, health behaviors, adjustment, emotional well-being, physical function, quality of life, and disease control.

Coping skills interventions have been found to increase the use of targeted coping behaviors and to result in improvements in both psychosocial and physical health outcomes, although their effectiveness varies considerably across intervention programs, individuals, and settings. A group-based coping skills intervention for skin cancer patients (Fawzy et al., 1993) serves as an example of a coping skills intervention that led to improvements in multiple quality of life and illness outcomes. This 6-week group intervention (relative to standard care) resulted in greater engagement in active behavioral and cognitive efforts, greater reductions in psychological distress, and greater improvements in immune function and survival rates.

Some interventions are designed to specifically target emotion regulation skills, including stress management strategies. Trials of emotion regulation interventions for individuals with cancer have demonstrated that participation in group interventions targeting emotional suppression and promoting adaptive emotion regulation strategies can reduce suppression tendencies and improve adjustment to cancer (Cameron et al., 2007). The cognitive-behavioral stress management (CBSM) program (Antoni et al., 2009) has been developed for use by individuals with a variety of chronic illnesses, including breast cancer, prostate cancer, HIV infection, and chronic fatigue syndrome. CBSM participants learn a variety of emotion regulation skills, including relaxation techniques, cognitive reframing strategies, and skills for improving use of social support. Trials testing the efficacy of CBSM consistently demonstrate that it increases targeted coping strategies and improves psychosocial adjustment, immune function, and quality of life.

Recent coping skills intervention research includes the development of programs designed for both individuals with chronic illness and their partners, other caregivers, and families. Couples-focused interventions typically provide training in communication skills for promoting effective dyadic coping with illness-related experiences and

relationship-focused coping for maintaining intimacy and relationship satisfaction (Manne and Ostroff, 2008). Family-focused coping interventions can be helpful for siblings of children with chronic illness, particularly through providing parents with skills for communicating information about the illness with their children and managing sibling emotions (Lobato and Kao, 2005).

Summary

Chronic illnesses are the leading cause of mortality worldwide. People living with a chronic illness must cope with the challenges of the illness and the distress it creates. Individuals cope with chronic illness using a variety of strategies. Problem-focused coping efforts involve reducing or resolving specific threats or negative consequences of the illness. Emotion-focused coping refers to the regulation of illness-related emotional distress. These coping strategies can co-occur, and they may interfere with one another at times. How engaged one is in coping efforts can impact management of the disease. Although disengagement from coping efforts often leads to maladaptive health outcomes, it can be adaptive when it involves disengaging from unattainable or unrealistic goals.

Accommodative coping is an engagement coping strategy reflecting cognitive adjustments in how one views the illness and the self, and it can facilitate adjustment when facing unavoidable illness consequences. Another cognitive restructuring strategy is meaning-focused coping, which reflects efforts to identify benefits and positive outcomes arising from the illness experience. Relationship-focused coping involves maintaining positive social support from partners through problem-focused efforts and empathic responding to concerns.

Individuals vary in their tendencies to engage in specific coping responses. Some individuals may naturally suppress emotions to mask feelings from others, which can lead to harmful effects on long-term health. Individuals may exhibit either a monitoring or blunting coping style. Monitors readily seek information, whereas blunters actively avoid it. One's illness beliefs also influence coping responses. Beliefs about illness identity, timeline, cause, consequences, and controllability all guide coping and behaviors.

Coping affects health through problem-focused efforts in managing the illness, as well as emotion-focused efforts in reducing distress and attenuating the effects of HPA and SAM system activation. Several interventions that target coping strategies have demonstrated improvements in psychosocial adjustment, immune function, quality of life, survival rates, and other important outcomes. Interventions that include patients and their spouses, children, and other family members have also produced positive results.

Coping with chronic illness has been, and remains, a topic germane to social and behavioral sciences in health, including health psychology and behavioral medicine. With increasing numbers of people living with a chronic illness at any given time, understanding the situational and dispositional factors related to illness management continues to be a pressing issue.

Chronic Pain: Models and Treatment Approaches

Dennis C Turk, University of Washington, Seattle, WA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article provides an overview of the current understanding of pain and its management. It reviews historical conceptualizations of chronic pain, namely, the biomedical, psychogenic, and motivational (secondary gain) models. It provides updated perspectives based on the gate control theory, operant conditioning, and cognitive-behavioral models and perspectives. An integrated, multidimensional model that integrates neurobiological, psychosocial, and behavioral features of these models is presented. The most common perspectives and treatments of pain based on the various models are described with an emphasis on the importance of a multidisciplinary approach to understanding and treating patients with complex chronic pain syndromes.

Pain has been of interest to philosophers, scholars, healers, and laypersons since the beginning of recorded history. Although there have been major advances in knowledge of sensory neurophysiology and the development of sophisticated pharmacological, surgical, and neuroaugmentative interventions, no treatments have proven to be consistently effective (Turk et al., 2011). Traditional medical models have been based on the assumption that there should be a close alignment between objective physical pathology and the extent of self-reported pain. Clinical observation and research have identified a number of challenges to this approach. Several alternatives to the pure biomedical conceptualization have been proposed, namely, psychological causation and maintenance models. These alternative models focus on the role of psychopathology and psychological and motivational factors in pain reports in the absence of objective physical pathology, and the role of environmental reinforcement in the maintenance of behavioral indicators of pain. These conceptualizations are, however, incomplete. Current models of pain (i.e., gate control and cognitive-behavioral) underscore the role of cognitive, affective, and behavioral factors, as well as somatic ones (Flor and Turk, 2011). Understanding, assessment, and treatment of patients experiencing pain based on comprehensive views emphasize the need to incorporate psychological and social variables with neurophysiology. The emphasis on treating patients with chronic pain has moved from cure to rehabilitation and self-management.

Introduction

Pain is one of the most common reasons for seeking medical care (Hart et al., 1995; Gureje et al., 1998). For many, pain is an adaptive response, warning of the potential for bodily harm. This signal helps to prevent further injury and tissue damage. However, research as well as common experience suggests that pain is much more than a mere barometer of the amount of tissue damage. Despite the universal experience of pain, it is a difficult phenomenon to define precisely. We have all seen instances where two people report radically different amounts of pain despite what appears to be an equivalent injury. Clinicians have also noted that soldiers report little or no pain after a combat injury until after they are removed from the battlefield. The wide variations in how people communicate their pain further complicate matters. Some may express pain by crying or groaning, whereas others are more stoic and handle their pain by gritting their teeth and suffering silently.

It is important to distinguish 'pain' from 'nociception.' Nociception is a physiological process by which transduction of sensory information is activated in specialized nerve endings that convey information about tissue damage (e.g., location, descriptive features) to the central nervous system. Pain, on the other hand, is an integrated perceptual process that requires a conscious organism. A person who is completely anesthetized does not report pain associated with a surgical incision. The International Association for the Study of Pain (IASP) recognizes the complexity of pain and treats it as a phenomenological experience unique to each person. According to the IASP definition, pain is "an unpleasant sensory and emotional experience normally associated with tissue damage or described in terms of such damage" (Merskey, 1986). In addition to this global definition, many commonly used pain terms and related phenomena have been described (Turk and Okifuji, 2001). For example, pain may be acute and a response to an identifiable trauma or disease, or it may be episodic and occur intermittently as in the case of migraine headache. Pain may also be relatively constant, extending for years and even decades. Unlike those with acute or recurrent pain, people with chronic pain may experience it 24 h a day, 365 days a year. **Table 1** includes a list of four classes of pain based upon timing and clinical implications.

In this article, I provide an overview of the current understanding of pain and its management. First I review the conceptualizations that have dominated views of pain historically. Then I describe current conceptualizations that integrate multifactorial aspects of pain. The article also focuses on psychosocial factors that have been shown to contribute to the subjective experience of pain as well as adaptation and response to treatment. Following the discussion of models of pain, I provide a historical overview of the most common perspectives and treatments of pain. I emphasize the importance of a multidisciplinary approach to understanding and

Table 1 Four types of pain

Transient pain:	Pain elicited by activation of nociceptive process but no significant injury is present and pain stops as soon as the activation ends. This type of pain is ubiquitous in everyday life and rarely is a reason to seek heath care. Examples: pain associated with injection for immunization
Acute pain:	Pain elicited by nociceptive activation at the site of injury or disease. This type of pain is often a reason to seek medical care. Examples: Postsurgical pain, pain associated with muscle sprain
Recurrent pain:	Episodic or intermittent pain. Each pain episode is relatively short lasting but recurs across an extended period of time. Examples: Migraine headaches, tic douloureux (trigeminal neuralgia), sickle cell crisis
Chronic pain:	Usually elicited by an injury but lasting for a long period of time after the original damage has been healed. At the chronic stage, no objective pathology may be present that can explain the presence of pain. Examples: Chronic low back pain, fibromyalgia

Source: Turk, D.C., Okifuji, A., 2001. Pain terms and taxonomies of pain. In: Loeser, J.D., Butler, S.H., Chapman, C.R., Turk, D.C. (Eds.), Management of Pain, third ed. Lippincott Williams & Wilkins, Philadelphia, pp. 17–25.

treating complex chronic pain syndromes. Finally, I provide an overview of the psychosocial strategies that incorporate behavioral and cognitive-behavioral perspectives with the goals of improving pain and functioning of people with persistent pain. It is not meant to be suggested, however, that pain is purely psychological or that physical factors are unimportant; in fact, they are most often necessary, at least initially. Rather, emphasis is put on psychosocial factors, as they have previously been less integrated into conventional thinking about chronic pain and have been shown to play a growing role in the maintenance of pain and disability over time. The psychological approaches described are almost always employed within the multidisciplinary treatment program (Turk et al., 2011).

Historical Conceptualizations of Pain

Over the centuries, many prominent scholars have attempted to uncover the mechanisms underlying pain. Perhaps among the most influential was the seventeenth-century French philosopher, René Descartes. Descartes conceptualized pain as the result of representation of a painful stimulus traveling along the nervous system starting at the periphery (the flame depicted in Figure 1 that will travel along the nerve from the periphery to the spinal cord eventually reaching the brain where it is acknowledged as 'pain'). Descartes's approach formed the basis for the mind–body dualism that plays a prominent role in the understanding and treatment of pain.

Biomedical (Pain = Physical Pathology) Model

The traditional biomedical view that continues to dominate is reductionist. This perspective assumes that every report of pain must be associated with a specific physical cause (e.g., pain caused by the flame in Figure 1). As a consequence, the extent of pain reported should be directly proportional to the amount of tissue damage. The expectation is that once the physical cause has been identified, appropriate treatment will follow

Figure 1 L'homme de René Descartes. Reproduced by permission of René Descartes Paris: Charles Angot, 1664.

and positive outcomes will be attained. Treatment typically focuses on removing the putative cause of the pain, or by chemically or surgically disrupting the pain pathways (cutting or blocking the transmission of signals from the periphery to the brain). According to this model, once the cause of the pain is removed or the pain pathways are blocked, pain should be eliminated. There are, however, several perplexing features of pain that do not fit neatly into the biomedical model with its suggestion of a one-to-one relationship between tissue pathology and symptoms. Most notably, not all pain accompanies observable pathology. For example, in over 85% of the cases of back pain, one of the most common pain conditions in Western countries, the cause of the pain is unknown (Deyo, 1986). Conversely, physical pathology does not necessarily cause pain. Diagnostic imaging studies identify significant pathology in up to 35% of people who are pain-free (Jensen et al., 1994). Thus, a paradox exists. On the one hand there are people without significant pathology who report severe pain and on the other there are people with objectively determined physical pathology who do not report the presence of any pain.

Psychogenic ('It Is All in Your Head') Model

According to the psychogenic model, pain, in the absence of physical pathology, is a result of the patient's inherent personality traits or psychological problems. The psychogenic view is posed as the flip side of the coin from the physical or biomedical model. From this perspective, if the report of pain occurs in the absence of, or is disproportionate to, objective physical pathology, then, *ipso facto*, the pain reports must have a psychological etiology. Thus, a dichotomy is posed, pain is either somatogenic or psychogenic.

Motivational (Secondary Gain) Model

A related conceptualization to the psychogenic model specifically focuses upon motivation. From this perspective, reports of pain in the absence of physical pathology are attributed to the desire of the person complaining to obtain some benefit such as attention, time off from undesirable activities, financial (disability) compensation (i.e., secondary gain), or to obtain prescribed medication with centrally reinforcing properties. Unlike the psychogenic model, in the motivational model, the assumption is that the person is consciously attempting to acquire a desirable outcome based on the complaint of pain. Thus, the report of pain in the absence of pathology is taken to be suspect and fraudulent. Simply put, the person who reports pain in the absence of objective pathology is pretending to experience pain in order to obtain a desired outcome.

Operant (Social Reinforcement) Model

The operant or social reinforcement model is based upon the behavioral learning paradigm in which the probability of exhibiting a specific behavior is observable, serves a communicative function, and depends on the consequences that follow the behavior. Behaviors are most likely to recur when they are reinforced by desirable consequences (e.g., attention, sympathy), by removal of something aversive (e.g., participating in undesirable tasks, work activity), or avoidance of some undesirable consequence. Fordyce (1976) suggested that certain behaviors associated with pain (e.g., limping, grimacing) could be reinforced to the point where the behaviors recur even when the original nociceptive stimuli is no longer present. Pain behaviors that are consistent with acute pain and that may be reflexive responses to noxious stimulation, may become chronic pain behaviors and be maintained even when there is no physiological basis for those behaviors. Thus, in this model, chronic pain is considered a manifestation of learned behaviors that need to be extinguished, whereas well behaviors, such as activity, need to be increased. The laws of operant learning are viewed as playing a central role in the maintenance of chronic pain behaviors. Other factors, such as physiology, emotions, and the persons' attitudes and beliefs, play little role in the operant model.

Multidimensional Conceptualization of Pain

The unidimensional models described fail to explain individual and situational variation in pain experiences. The article will now focus on more contemporary models of pain with multifactorial bases.

Gate Control Theory

Melzack and Wall (1965) developed the gate control theory that integrated physical and psychological factors regarding pain experience. Briefly, the gate control theory proposes that a mechanism in the dorsal horn of the spinal cord acts as a 'gate' that can inhibit or facilitate transmission of nerve impulses from the periphery to the brain. Melzack and Wall postulated that not only injury sites at the periphery influence the gating mechanism but also people's emotional states. They suggested that the reticular formation in the brain functions as a central biasing mechanism inhibiting the transmission of pain signals. Psychological factors that affect the reticular formation may modulate the pain experience.

Melzack and Wall emphasized the modulation of inputs in the dorsal horn of the spinal cord and on the dynamic role of the brain in pain processes and perception. As a result, the gate control theory integrates psychological variables such as past experience, attention, and other cognitive activities into current research on and therapy for pain. Prior to this formulation, psychological processes largely were dismissed as merely reactions to pain. This new model suggested that severing nerves, the putative pain pathways, was inadequate as a host of other factors modulated the input. Perhaps the major contribution of the gate control theory was that it highlighted the central nervous system as playing an essential role in the perception and interpretation of nociceptive stimuli associated with the experience of pain.

The physiological details of the gate control model have been challenged and it has been suggested that the model is incomplete. As additional knowledge has been gathered since the original formulation of the gate control model, specific points have been disputed and physiological details of the model have been refined. The conceptual aspects of the gate control theory have, however, proved remarkably resilient and flexible in the face of accumulating scientific evidence. The gate control model still provides a powerful summary of the phenomena observed in the spinal cord and brain, and has the capacity to explain many of the most puzzling problems encountered in the clinic. The gate control theory has had enormous heuristic value in stimulating further research in the basic science of pain mechanisms and in spurring new approaches to treatment.

Cognitive-Behavioral Model

The focus of the cognitive-behavioral model is on the person's own subjective perspectives (e.g., attitudes, beliefs, expectations) and feelings about their plight (Turk et al., 1983; Flor and Turk, 2011). The model assumes that, although nociceptive stimuli precede pain, how the person perceives the nociceptive event forms a total pain experience by interacting with the sensory event. For example, negative and pessimistic views by people about their pain condition (e.g., 'It is hopeless and it will never get better.') and their capabilities for managing pain and stress (e.g., 'There is absolutely nothing I can do about my pain.') are likely to exacerbate their emotional distress and sense of disability. Similarly, if one views pain as inevitable (e.g., 'I was injured, that is why I hurt.'), attention to sensory events may become pronounced, and as a consequence, relatively subtle sensory information may be interpreted as being painful.

The cognitive-behavioral model also acknowledges the effects of physiological factors and the environment on behaviors and of behaviors on thoughts and feelings. Reporting of symptoms to family and health care providers is influenced by how people view their pain problem and, of course, physical pathology.

The basic assumption of the cognitive-behavioral model is that people are not passive entities who simply react reflexively to nociception or social reinforcement, but actively engage themselves in defining the experience. Based upon past learning and medical history, people develop subjective representations of illness and symptoms – 'schemas.' These schemas become the filters through which people process new sensory stimulus (Cioffi, 1991). Beliefs about the meaning of pain and one's ability to function despite pain are important aspects of pain schemas. When confronted with pain, people draw causal, covariational, and consequential inferences about their symptoms based upon their own schematic references. For example, if the schema includes a strong belief that all physical activities must be ceased when experiencing pain and that pain is an acceptable justification for neglecting domestic and occupational responsibilities, poor adaptation and coping are likely to result (Williams and Thorn, 1989).

Treatments

As has been discussed previously, pain is a complex phenomenon and diverse in its nature and degrees of associated impairment. It is therefore important to know the objectives of treatments for pain. Many pain states are expected to remit over time with little intervention required. Some types of acute pain may require surgical or pharmacological therapy to treat underlying pathology or to block noxious sensory information. A more comprehensive plan is required for treating people with chronic pain. Many people with chronic pain live with their pain for years, and the adverse effects of pain may be generalized across all aspects of their lives, familial, social, occupational, as well as physical. Given the multilayered problems associated with pain, treatment goals become more global. Rather than treating pain, it becomes necessary to treat people with chronic pain.

Historical Approaches to Treatment

The earliest approach to treating pain was aligned closely with unimodal views, particularly those based on the biomedical model. Pain was thought of as reflecting a physical problem. Early treatment approaches focused on the idea that something had to be removed or signals had to be interrupted to bring about relief from pain. The earliest reference to medication is referred to in an ancient Egyptian text dating back to 1550 BC where the goddes Isis recommended the use of opium to relieve Ra's headache (Bonica, 1990). Ancient pain treatments have included crocodile dung; oils derived from ants, earthworms, and spiders; spermatic fluid from frogs; and moss scraped from the skull of a victim of a violent death. A quick surf of the Internet will reveal that many equally esoteric preparations are endorsed readily even today.

The most common contemporary treatment approaches continue to be based primarily on the biomedical model of pain involving pharmacotherapy (with new drugs touted on an almost weekly basis) or surgery performed along nearly every site of the nervous system including the periphery (sympathectomy), the spinal cord (percutaneous cordotomy, destructive neural blockade), and the brain (thalamatomy, prefrontal lobotomy). Although current methods are more sophisticated than the ancient ones, the basic principles remain the same – alteration of an alleged physical cause should result in symptomatic improvement. Some modalities are quite helpful and a great many people suffering from acute and cancer pain have benefited from those advances in pain medicine and surgery. However, surgery and pharmacotherapy are not panaceas and do not result in adequate control of pain in all cases (Turk et al., 2011).

In contrast, some primitive treatment methods focused on the cause of pain being purely psychogenic. The assumption was that if no physical cause could be detected, then the pain must be caused by emotional disturbance that required treatment and once psychological problems were resolved, the pain would resolve. Such a psychogenic bias could be seen in the fourth version of the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV; American Psychiatric Association, 1994). Two types of pain disorders were listed as mental disorders: "Pain Disorder Associated with Psychological Factors" and "Pain Disorder Associated with Both Psychological Factors and a general medical condition." In both cases, pain is the primary complaint, with psychological factors being considered important in the onset, severity, exacerbation, or maintenance of the pain. A somewhat presumptuous assumption underlying these disorders is that the 'appropriate' physical etiology of chronic pain must be identifiable (e.g., free from psychological factor) or patients are suffering from a psychiatric disorder. The assumption ignored the current consensus that pain is not a pure sensory experience but is inherently a biopsychosocial phenomenon resulting in an intense, subjective experience of discomfort. The current version of the DSM (DSM-V; American Psychiatric Association, 2013), therefore, acknowledges that there is a lack of evidence that such distinctions can be made with reliability and validity, and takes the approach that individuals with chronic pain would be appropriately diagnosed as having somatic symptom disorder, with predominant pain. For others, psychological factors affecting other medical conditions or an adjustment disorder would be more appropriate.

Comprehensive Approaches to the Treatment of the Person with Chronic Pain

The recognition of pain, particularly chronic pain, as a major health care issue, has resulted in the development of a growing number of specialists and specialized facilities offering treatments for pain over the last few decades. Comprehensive, multidisciplinary treatments involving teams of professionals (physicians, psychologists, physical therapists, occupational therapists, vocational therapists, and nurses) have been developed for the treatment of patients with the most recalcitrant problems. Flor et al. (1992) summarized the major characteristics of these patients as those with 7 years of pain history and at least one failed surgery. These patients are likely to be unemployed, receiving disability payments, and present an array of psychosocial and motivational issues. In addition to the suffering associated with chronic pain, these patients present socioeconomic difficulties for society due to loss of productivity and costs associated with disability payments and medical care.

In the following, the focus will be on the pain management approaches that have been developed based upon the psychological models described earlier. Although these interventions can be used separately, with few exceptions (e.g., biofeedback for tension-type headache) unimodal approaches are less effective than comprehensive rehabilitation programs (Turk et al., 2011). Typically, the psychological approaches are part of more comprehensive rehabilitation programs in which psychologists work together with therapist from other disciplines (e.g., physicians, physical therapists).

The multidisciplinary rehabilitation programs are philosophically distinct from unimodal medical and surgical treatments. The first and most critical distinction is that the major goals of the multidisciplinary treatment programs extend beyond pain relief. Rather, they focus on physical and psychological functioning as well.

Overall, rehabilitation programs that incorporate a significant psychosocial component are most effective in improving patient functioning, returning patients to work, reducing use of analgesics, reducing health care utilization, and reducing disability costs (Okifuji et al., 1998). 'Cure' of pain (e.g., total relief from pain) is, unfortunately, rarely attained. Reduction of pain is usually only moderate but comparable to that observed with usual medical and surgical approaches that are more invasive and have increased likelihood of iatrogenic consequences (Turk et al., 2011).

Treatment Based on the Operant Model

As noted previously, the operant model of pain focuses upon pain-related behaviors believed to be maintained by social reinforcement. Such behaviors are considered to be maladaptive and thus need to be eliminated. As discussed, reinforcers are the consequences of behaviors that increase the likelihood that behaviors will be repeated. Thus, treatment involves eliminating the rewarding consequences of pain behaviors and increasing the positive responses for activity and other well behaviors. In these programs, moaning, grimacing, and other pain behaviors are ignored. Usual activities of daily living and functional exercises are prescribed and positively reinforced. Medications are made time-contingent, rather than prescribed on an 'as needed' (prn) basis that is believed to reinforce positively the pain behaviors. Simultaneous with the attempts to extinguish pain behaviors, operant treatments are designed to help patients acquire a set of new, more adaptive, behaviors. Quota-based exercise programs with gradually increasing functional activities form the core of operant treatment.

Although operant factors may play an important role in the maintenance of disability, the model has been criticized at two levels. First, it fails to integrate factors other than reinforcement, such as sensory, emotional, and cognitive factors, in the overall pain experience. Second, the assumption that pain behaviors are acquired, maintained, and extinguished solely through environmental reinforcement contingencies is questioned. For example, physical signs, patients' self-efficacy beliefs, and depression are also reportedly related to pain behaviors (Buckelew et al., 1953).

Pain behaviors have been considered to be maladaptive manifestations of pain, guided by an incentive for attention or avoidance of physical activity. However, pain behaviors may be functional if indeed the behaviors protect patients from further injury or exacerbation of pain. Determination of whether an overt pain behavior in a given patient is functional or maladaptive needs to be based upon careful assessment of various factors associated with his or her pain conditions not just the reinforcement contingencies. Despite the criticisms, operant-based treatments have been reported to be successful in reducing overt pain behaviors, increasing well behaviors, and decreasing analgesic medication (e.g., Thieme et al., 2006).

Treatments Based on the Cognitive-Behavioral Model

As noted earlier, the cognitive-behavioral model of pain acknowledges the importance of cognitive variables interacting with sensory, affective, and behavioral factors to establish, maintain, and exacerbate the pain experience. The nature of specific techniques may vary from program to program; however, the primary goals of the cognitive-behavioral approach are relatively uniform (i.e., enhancement of patients' sense of control over their symptoms, increased use of adaptive skills to cope with pain and stress). Cognitive-behavioral therapy is designed to assist patients to identify, evaluate, and correct maladaptive conceptualizations and dysfunctional beliefs about themselves and their predicament. Additionally, patients are taught to recognize the connections linking cognition, affect, and behavior along with their joint consequences. Patients are encouraged to become aware of and to monitor the impact those maladaptive thoughts may have in the maintenance and exacerbation of maladaptive behaviors (see **Table 2** for common maladaptive thoughts). The central emphasis of the cognitive-behavioral approach is on patient self-management.

The cognitive-behavioral approach consists of four interrelated phases. These include (1) reconceptualization, (2) acquisition of coping skills and self-management strategies, (3) skill consolidation, and (4) generalization and maintenance (Flor and Turk, 2011; Turk et al., 1983). The first phase, reconceptualization, uses cognitive restructuring, a method that encourages people to identify and change maladaptive

Table 2 Common examples of cognitive errors

Overgeneralization: Extrapolation from the occurrence of a specific event or situation to a large range of possible situations. 'This coping strategy did not work; nothing will ever work for me'
Catastrophyzing: Focusing exclusively on the worst possibility regardless of its likelihood of occurrence. 'My back pain means my body is degenerating and falling apart'
All-or-none thinking: Considering only the extreme 'best' or 'worst' interpretation of a situation without regard to the full range of alternatives. 'If pain is not completely gone, I cannot do anything right'
Jumping to conclusions: Accepting an arbitrary interpretation without a rational evaluation of its likelihood. 'The doctor did not return my call today. He thinks I am a hopeless case'
Selective attention: Selectively attending to negative aspects of a situation while ignoring any positive factors. 'Physical exercises only make my pain worse'
Negative predictions: Assuming the worst. 'I know I will not get better even with all these therapies and everyone will dislike me for that'
Mind Reading: Make arbitrary assumptions about others without finding out what others are thinking. 'My husband does not talk to me about my pain because he does not care about me'

thoughts and feelings that are associated with the experience of pain. The crucial element in successful treatment is bringing about a shift in the patient's thought processes, away from well-established, habitual, and automatic but maladaptive thoughts toward more hopeful and rational ones. Cognitive restructuring helps foster the reconceptualization by helping patients to become aware of the role thoughts and emotions play in potentiating and maintaining stress and pain. The aim of this phase is to combat the sense of demoralization that many with chronic pain experience. Generally, the process of cognitive restructuring begins with a presentation of a situation or event that provoked a pain-related response. The situation is dissected to identify key thoughts and feelings that precede, accompany, and follow an episode or exacerbation of ongoing pain and pain-related problems. Then, patients are encouraged to challenge the legitimacy of the thoughts – Was it true? Was it reasonable? Was it the only way to respond? What alternatives are available? and so on. Patients are instructed to gather evidence for or against their own maladaptive automatic thoughts. Alternatives are discussed, with the suggestion that different ways of thinking can affect mood, behavior (e.g., reducing physical activity leading to greater disability), and even physiological activity (e.g., increase muscle tension and thereby exacerbate pain).

The second phase is the acquisition of self-management skills. A wide variety of techniques have been shown to be effective for reducing suffering and disability. Some of these strategies are self-regulatory skills (e.g., relaxation, controlled breathing, and attention diversion) that allow pain sufferers to regulate their own physiological responses that may be involved in the maintenance and exacerbation of pain. Other self-management strategies include stress-reduction skills (e.g., problem solving, behavioral rehearsals) that allow people with chronic pain to effectively manage the stress-inducing thoughts, behaviors, and emotions that trigger pain, emotional distress, and other maladaptive responses. Instead of being a passive recipient of a medical intervention (e.g., medication, anesthetic nerve block), patients now learn to use self-management strategies to play an active role in managing the myriad of problems created by the presence of persistent pain. Research has suggested that there is no one specific coping skill that best manages pain and disability (Fernandez and Turk, 1992). It is recommended generally that patients with chronic pain should be taught various types of coping skills to help them acquire a range of options.

Phase 3 is skill consolidation. During the skill-consolidation phase, patients practice and rehearse the skills that they have learned during the acquisition phase and apply them outside the hospital or clinic. Practice may start with mental rehearsal, during which patients imagine using the skills in different situations. Therapists can make use of role-playing, in which patients rehearse learned skills in situations that mirror their home environments. Therapists may start with a relatively easy example and then introduce scenarios that are progressively more realistic. The importance of skill consolidation through home practice cannot be overstated. When patients practice skills at home, it is useful for them to record their experiences including any difficulties that arise. Once problems associated with using the newly acquired skills are identified, these become targets for further discussion.

The final stage is phase 4: the preparation for generalization and maintenance. To maximize the likelihood of maintenance and generalization of treatment gains, therapists focus upon the cognitive activity of patients as they confront problems throughout treatment (e.g., failure to achieve goals, plateaus in progress, recurrent stress). These circumstances are used as opportunities to assist patients to learn how to handle setbacks and lapses because they are probably inevitable parts of life and will occur after the termination of the treatment. In the final phase of treatment, discussion focuses on ways of predicting and dealing with symptoms and related problems following treatment termination. Patients are encouraged to anticipate future problems, stress, and symptom-exacerbating events during treatment and to plan how to respond and cope with these problems.

Since self-initiating pain management is a key factor in pain rehabilitation, some type of cognitive behavioral approach generally is included in a multidisciplinary pain program. Cognitive-behavioral approaches have been demonstrated to be effective with a wide range of debilitating pain syndromes including low back pain (Gatchel and Rollings, 2008), arthritis (Astin et al., 2002), fibromyalgia (Thieme et al., 2006), and temporomandibular disorders (Turner et al., 2006). Moreover, these methods have been shown to be effective with children (Palermo, 2011) and geriatric samples (Lunde et al., 2009).

Summary

This article reviewed the definition of pain and the historical context within which pain has been conceptualized, made a distinction between nociception (a sensory process) and pain (a perception), and described the most common conceptualizations based on the unidimensional and multidimensional models of pain. It was noted that treatment strategies have closely followed the conceptualizations of pain and have included unidimensional modalities (i.e., biomedical, psychogenic) and progressed to multidimensional modalities.

Although pain generally is considered a physical phenomenon, pain involves various cognitive, affective, and behavioral features. These psychological factors are important not only in determining the perception of pain, but also defining disability and patients' general well-being. It should be clear from the review that pain has three main components, physical, psychosocial, and behavioral, that interact to define the unique pain experience. Because the pain experience is subjective and idiosyncratic, it cannot be understood without evaluating how patients perceive and appraise their conditions. A complete clinical picture involves consideration of how patients view their plight. By understanding the phenomenology of chronic pain and disability, effective treatment can be planned to alleviate persistent and debilitating pain, and improve physical and psychological functioning, thereby reducing the disability that accompanies chronic pain.

Abstract

Estimating age in the archaeological record is the primary step in understanding the human past. Chronology provides a temporal dimension that distinguishes archaeology, paleontology, and geology from the disciplines of ethnography and ethnology. Increasingly better-defined methods of dating have radically enhanced our ability to address questions of cultural identity and ethnicity, as well as cultural change; an understanding of the primary methods that date the past is still critical to interpreting social process. The facility to correlate an event or episode with an absolute point in time is crucial in solving many archaeological problems. A variety of methods can be used to establish chronology in archaeology. Foremost among these are stratigraphic techniques, dating based on animal and plant remains, chemical accumulation, and temperature effects, as well as radiometric and radiation dating. The various techniques are applicable under certain conditions, and yield variable results based on context and dated material. All these dating techniques are focused on generating an absolute or relative chronology as the first step in understanding the past.

Introduction: Estimating Age in the Archaeological Record

Of the twenty or so dating methods employed in twenty-first-century archaeology, the US Congressional Office of Technology Assessment (OTA) report on *Technologies for Prehistoric and Historic Preservation* (US Congress, OTA, 1986) listed only seven and highlighted two radiocarbon and archaeomagnetic techniques; see Taylor 2000, pp. 75–60. In many regions of the world, radiocarbon, dendrochronology, obsidian hydration, and archaeomagnetism are the most common physical dating methods used, presumably in that order, but often together as a group providing redundant checks on one of the most important goals of archaeology – providing a framework of time, a chronology, upon which a rational reconstruction of the past can be built. Regardless of an archaeologist's theoretical or political perspectives, the first goal is to order regional prehistoric or historic sites, a single site, or a portion of the site into meaningful cultural and chronological segments. Chronology is a primary goal, but should not be confused with the intent of reconstructing the past, regardless of what an archaeologist's definition of the ultimate purpose may be.

During the formative cultural historic perspective in archaeology in the first half of the twentieth century, constructing regional and site-oriented chronologies became the primary goal of archaeology, particularly in North America and the United Kingdom (Trigger, 1989). A dissatisfaction with this rather unilineal explanation of the past stirred archaeologists to look beyond simply constructing chronologies and to begin to understand process and social relationships in the past. Dating methods and the construction of cultural chronologies, however, have remained the basement upon which archaeologists build their understanding of social process through time.

While it would be optimal to discuss all the potential dating methods available to archaeologists, this is not possible in a short synopsis. The most commonly used methods, and those showing promise, will be covered here (see **Table 1** and **Figure 1**). Refer to the publications in the bibliography for more detailed treatments.

Archaeological Stratigraphy

Stratigraphic relations have always been the primary method to infer the relative age of artifacts within a site. Stratigraphy is defined here as the study of the spatial and temporal relationships between the sediments and the soil (Waters, 1992: pp. 60–61). Much of this section's discussion can be more robustly understood by referring to the entry *Geoarchaeology*; an awareness of the geological processes of archaeological site formation is crucial to an understanding of dating archeological sediments. Indeed, the methods used by Quaternary geologists to date sediments include most of the methods used by archaeologists and discussed here (see **Figure 1**). Stratigraphic studies of archaeological sites are designed to define objectively and categorize the sediments and soils, the contact units between them, and the amount of time they represent, as well as their relationship to the surrounding sediment history.

Archaeological stratigraphy is based on the geological concepts of the law of superposition, which states that older sediments are emplaced at a lower level than more recent sediments. Therefore, sites, features, and artifacts residing in lower levels are, by definition, older than those in upper levels. This conceptual framework in archaeology appears to have begun with John Frere in 1797 attempting to understand the relationship between stone axes in a sedimentary sequence in England: "The manner in which ... [the hand axes] lie would lead to the persuasion that it was a place of their manufacture and not of their accidental deposit ... It may be suggested that the different strata were formed by inundations happening at distant periods" (Frere in Rapp and Hill, 1998: p. 5).

This idea that features or artifacts found within a site in the same stratigraphic level are contemporaneous forms the foundation upon which archaeological stratigraphy is based.

Figure 1 Commonly used dating methods in archaeology. Those marked with (*) are discussed in some detail in this article. Source: Adapted from Waters, M.R., 1992. Principles of Geoarchaeology: A North American Perspective. University of Arizona Press, Tucson, AZ.

In early twenty-first century archaeology, the various relative and absolute dating methods such as radiocarbon or archaeomagnetic dating are used to verify this assumption and produce a site chronology (see **Figure 2**). **Figure 2** shows a simple stratigraphic profile of a single excavation unit with the relative positions of natural and cultural features, and the position of radiocarbon dates recovered from the various levels. Note that the radiocarbon dates indicate that, in general, the stratigraphy is intact in that the oldest dates are at the bottom and the latest dates at the top, except for one date (CAMS 43177) at 3690 ± 50 BP which seems to be out of sequence and suggests 'small-scale' disturbance probably caused by the digging of the pit structure during the later ceramic period (Shackley et al., 2000).

Time-sensitive artifacts, such as previously dated pottery or projectile point types, can be used as *index fossils* within the stratigraphic column to create a relative chronology within the site. The stratigraphic example discussed above also used index fossils, in this case projectile point types, to add another chronological piece of information. In Level 8, where the early radiocarbon date as well as some more recent radiocarbon dates were recovered, Middle Archaic as well as Late Archaic projectile point forms were recovered; both confirming the time range suggested by the radiocarbon date ranges (**Figure 2**, Shackley et al., 2000). In this instance the stratigraphy, radiocarbon dates, and index fossils all contributed to an understanding of the site chronology and the integrity of the archaeological deposit.

Constructing Stratigraphic Chronologies: Competing Ideas

It is important to note, however, that there is considerable recent controversy over the proper method to employ in the interpretation of archaeological stratigraphy (Farrand, 1984; Harris et al., 1993; Stein, 1987; Waters, 1992). Archaeological stratigraphic codes similar to geological stratigraphic codes and methodologies have been proposed but not generally adopted, since many geoarchaeologists are convinced that the existing geological code is adequate for archaeological research (see Stein, 1987). More recently, Harris has proposed an 'archaeological tool' to understand archaeological stratigraphy called the 'Harris Matrix,' essentially a simple postexcavation way in which to understand the relationships between stratigraphic units in a single diagram as reflected on paper, or more recently in digital form (see Harris et al., 1993). Farrand (1984) and others, mainly geologists, have questioned Harris's assumption that archaeological stratigraphy is primarily culturally conditioned rather than geologically determined. In a Harris Matrix analysis the relationship between stratigraphic units is based mainly on index fossils, for example the relationship between artifacts and features, rather than geological features or context – essentially emphasizing content rather than structure. Despite criticism from many geoarchaeologists, the Harris Matrix analysis has become increasingly popular with archaeologists working in varieties of geological and cultural contexts worldwide, particularly in Europe. The growing popularity of the Harris Matrix approach will probably continue, particularly in small site settings where a larger geological view is difficult to obtain or not necessarily relevant.

Sidereal Dating Methods

Sidereal dating methods include historical records, glacial varve dating, and dendrochronology. While only dendrochronology will be discussed here, glacial varve dating is quite useful in the upper latitudes, and in some cases may be quite precise. Historical records are a basic dating tool in historic and ethnohistoric archaeology, in addition to the social information they may contain.

Dendrochronology

The science that uses annual tree rings for dating past events and reconstructing past environmental conditions has undergone explosive growth in recent decades (Dean, 1997). While dendrochronology as an archaeological dating tool enjoyed tremendous expansion in the 1990s, particularly in western North America, Europe, Siberia, and the eastern Mediterranean, it is used wherever appropriate trees occur and a sequence has been established. Most importantly,

directly dated tree rings have been instrumental in the calibration of the radiocarbon timescale discussed below. This process indicated that the radiocarbon chronology underestimates the true ages of materials older than 2000 years and that ^{14}C dates must be corrected.

The technique is based on the concept that each year (four seasons) a tree will accumulate one growth ring, and that that ring's attributes reflect the specific climatic regime of that year. Since each year is essentially a unique climatic record, the attributes of the tree ring (thickness of inner and outer bands) are correspondingly unique. In trees, particularly fast-growing conifers, the progression of rings from pith to circumference presents an 'unalterable temporal order, and the production of but one ring per year provides the incremental regularity necessary to establish a fixed [and absolute] time scale' (Dean, 1997: p. 34). More than 180 tree and shrub species worldwide possess the attributes required for successful dendrochronological studies: visible and unambiguous ring definition, production of a set number of rings (generally only one) per year, mainly climate-controlled growth, and the presence of useable morphological features that allow for ring comparison. Cross-dating, matching patterns of ring variation among trees, is the necessary principle of dendrochronology. A sequence within a region is derived from overlap between cut trees as well as archaeological specimens, sometimes with great time depth into the thousands of years. While this process is apparently simple, the application necessarily requires precision. At the turn of the twenty-first century, image analysis technology was being used to develop electronic workstations, including image databases in laptop computers, perform routine comparisons between the database and archaeological wood samples similar to techniques used in obsidian hydration analysis.

Today, in a number of regions of the world (upper altitudes in the North American Southwest, Western Europe, the Eastern Mediterranean) dendrochronology forms the backbone of chronometric dating. When available, dendrochronology provides an absolute chronology that anchors other dating techniques.

Isotopic Dating Methods

Perhaps the one area of dating that has seen the greatest advances recently are techniques based on radioactive decay: ^{14}C, K-Ar, and $^{40}Ar/^{39}Ar$. Advances in accelerator mass spectrometry and laser fusion have propelled these techniques into the forefront of the arsenal of methods used to deal with time in the archaeological record. Importantly, ^{14}C is generally restricted to dating the last 50 000 years and $^{40}Ar/^{39}Ar$, previously restricted to time periods near and over 1 million years, are now nearly overlapping with $^{40}Ar/^{39}Ar$ using the laser fusion method and yielding younger and younger ages. These methods do have limitations, but the organic and mineral restrictions are being transcended almost daily.

Radiocarbon Dating (^{14}c)

Given that the greatest level of human activity occurred after the evolution of modern Homo sapiens, in the last 45 000 years or so, radiocarbon dating has become the most commonly relied upon dating method in archaeology (Taylor in Taylor and Aitken, 1997). Radiocarbon dating, now in its fifth decade of general use, is a primary tool used by archaeologists and Quaternary geologists to date the past.

The Radiocarbon Method

There are three principal isotopes of carbon which occur naturally: ^{12}C, ^{13}C (both stable), and ^{14}C (unstable or radioactive). The radiocarbon method is based on the rate of decay of the radioactive or unstable carbon isotope 14 (^{14}C), which is formed in the upper atmosphere through the effect of cosmic ray neutrons upon nitrogen 14. The reaction is: $^{14}N + n \Rightarrow {}^{14}C + p$ (where n is a neutron and p is a proton).

The ^{14}C formed is rapidly oxidized to $^{14}CO_2$ and enters the Earth's plant and animal lifeways through photosynthesis and the food chain. Plants and animals which utilize carbon in biological food chains take up ^{14}C during their lifetimes. They exist in equilibrium with the ^{14}C concentration of the atmosphere; that is, the number of ^{14}C atoms and nonradioactive carbon atoms stays approximately the same over time. As soon as a plant or animal dies, they cease the metabolic function of carbon uptake; there is no replenishment of radioactive carbon, only decay.

Libby, Anderson, and Arnold (Taylor and Aitken, 1997) first discovered that this decay occurs at a constant rate. They found that after 5568 years half the ^{14}C in the original sample will have decayed, and that after another 5568 years half of that remaining material will have decayed, and so on. The half-life ($t_{1/2}$) is the name given to this value, which Libby measured at 5568 ± 30 years. This became known as the Libby half-life. After 10 half-lives, there is a very small amount of radioactive carbon present in a sample. At about 50 000 to 60 000 years, then, the limit of the technique is reached (beyond this time, other radiometric techniques must be used for dating, such as $^{40}Ar/^{39}Ar$, as discussed above). By measuring the ^{14}C concentration or residual radioactivity of a sample whose age is not known, it is possible to obtain the number of decay events per gram of carbon. By comparing this with modern levels of activity (1890 wood corrected for decay to AD 1950) and using the measured half-life, it becomes possible to calculate a date for the death of the sample.

It follows from this that any material which is composed of carbon may be dated. Herein lies the true advantage of the radiocarbon method – it is able to be uniformly applied throughout the world. A list of the tremendous quantity of organic material that can be dated by radiocarbon is available at the University of Waikato's radiocarbon Web site, a standard for understanding the technique: http://c14.sci.waikato.ac.nz/webinfo/int.html.

Calibration and Radiocarbon Dating

As mentioned above, there are a number of effects that can cause errors in the measurement of radiocarbon dates. For example, shell, in constant contact with more recent atmospheric carbon, will generally yield young dates; conversely a shell artifact deposited in older limestone sediments will obtain a much older date than its actual death. These reservoir effects are in part mitigated by the use of various calibration algorithms, such as the CALIB (2001) and OxCal (2001) programs, both available online.

When a radiocarbon lab returns a date from a sample such as 5568 BP, it does not mean that it dates to 3619 BC, because the

true half-life of radiocarbon is 5730 years, and, more importantly, the proportion of radiocarbon in the atmosphere has varied through time, as discussed above. So the calibration utilities are written to allow for differential in the absorption of ^{14}C by different materials (i.e., marine shell versus wood charcoal), and to allow for different atmospheric effects. Using the CALIB 4.2 calibration, a radiocarbon assay of 5568 BP with a 1 standard deviation of 55 years on wood charcoal yields a date of:

$$68.3\left(1\sum\right)\text{cal } 4454-4416 \text{ BC}$$

$$\text{probability distribution } 0.409$$

$$4408-4354 \text{ BC } 0.591$$

Note that there are two dates with ranges of a number of years. The range includes the one standard deviation, and the two dates are due to multiple intercepts on the calibration curve. We can be 68.3% certain that the dates fall either from 4454 to 4416 BC or from 4408 to 4354 BC. There are multiple possible dates because the radiocarbon date of 5568 BP intercepts the calibration curve at more than one point. Due to the perturbations in the absorption of radiocarbon over the millennia, the variance is sometimes full of 'wiggles' on the curve, so placement can occur at two or more points.

Radiocarbon dates are reported in a standardized method, as shown in Table 2. The convention calls for reporting the provenience of the sample, the laboratory number, the radiocarbon age, and then the calibrated (in this case dendrocalibrated) age at one or two standard deviations (note that most of these dates yielded multiple intercepts). The calibration method used and any further contextual information should also be supplied.

Accelerator Mass Spectrometry (AMS) and Radiocarbon

From the inception of radiocarbon dating, ^{14}C ages of samples were calculated by decay counting in mainly scintillation counters. This requires a relatively large sample, depending on the amount of carbon remaining in that sample. By the late 1970s a number of researchers discovered that when accelerating sample atoms in the form of ions to much higher energies in particle accelerators, a much smaller sample was required to derive confident dates – in most cases only milligrams instead of tens of grams for scintillation counting. Both cyclotron and tandem accelerator mass spectrometers have been used to accomplish this, with tandem accelerators becoming the most popular. One additional advantage of acceleration is that the 'stripping process' disassociates all molecular species with the result that carbon isotopes can be isolated, and contamination minimized. AMS ^{14}C dating theoretically may push the time frame back to 100,000, effectively overlapping $^{40}Ar/^{39}Ar$ laser fusion dating (Taylor and Aitken, 1997).

Radiation Dating Methods

As with most of the other types of dating methods, radiation dating methods have undergone tremendous advances in the last decade, although many of these methods remain somewhat controversial in their applications. Electron spin resonance (ESR) and thermoluminescence (both based on the accumulation of trapped electrons in minerals), and fission track dating (produced when alpha particles are created by spontaneous fission of ^{238}U leaving a damage trail), have all had their detractors, but have recently gained recognition as techniques that are useful in dating materials not readily possible with the more accepted technology, for example glass, tooth enamel, and pigments (see Table 1). Archaeomagnetic dating has gained wide acceptance in many regions of the world and deserves some discussion.

Archaeomagnetic Dating

Archaeomagnetic and paleomagnetic dating both rely on the phenomenon of the frequent and predictable shifts in the Earth's magnetic polarity in space and time. The premise for the method states that the Earth's magnetic poles wander (show

Table 2 Recent pre-3000 BP (RCY) maize and cucurbit AMS ^{14}C dates from the American Southwest showing reporting conventions

[1]The 2σ dendrocalibrated minimums (intercepts) and maximums are based on a bidecadal correction in calendar years BP, rounded to the nearest decade, from Stuiver and Reimer (1993, version 3.0.3c, Method A). The maize dates are not corrected for C4 carbon uptake and can actually be up to 240 years older than reported here assuming –10 0/00. 2 This date and context is somewhat suspect, but was associated with a similar charcoal date at Los Pozos in the Tucson Basin (Freeman A.K.L., 1997. Middle to Late Holocene stream dynamics of the Santa Cruz River, Tucson, Arizona: Implications for human settlement, the transition to agriculture and archaeological site preservation. Ph.D. thesis, University of Arizona, Tucson, AZ, see also Gregory, D.A., Adams, J.L. (Eds.), 1999. Excavations in the Santa Cruz River Floodplain: The Middle Archaic Component at Los Pozos. Center for Desert Archaeology, Tucson, AZ.). 3 This date on a *Cucurbita sp.* is probably from a wild species. However, three specimens of maize were dated to over 2800 RCY BP (Hard, R.J., Roney, J.R., 1998. A massive terraced village complex in Chihuahua, Mexico, 3000 years before present. Science 279, 1661–1664.).

secular variation) or flip (reverse direction), and that these variations provide a temporal fingerprint that can be detected in rock and sediments. Iron dipoles in minerals in soft sediments align themselves parallel with the Earth's magnetic field at the time of deposition until the sediment solidifies, for example as baked clay in a hearth. This creates detrital remnant magnetism whose direction and intensity precisely reflects the Earth's magnetic field at the time of deposition; and by matching their magnetic orientation to a master record, it is possible to derive a relatively accurate date. This master curve has been derived for the last 10 000 years. Archaeomagnetism is useful in dating material, as appropriate, when other useful dating material, appropriate for other techniques is absent.

Chemical, Temperature, and Water Affected Dating Methods

Some of the more controversial dating methods are those that are based upon changes in chemicals, temperature, and/or water for calibration. Amino acid racemization held great promise for dating organic materials, but is not generally reliable, while obsidian hydration dating, which was also promising, has become equally problematic.

Obsidian Hydration Dating

Obsidian, a quenched rhyolite glass is common along plate boundaries and volcanic arcs where crustal remelting has occurred. A glassy brittle rock with remarkable cutting properties, it has been used throughout human history in the production of stone tools (Shackley, 1998). Obsidian is a noncrystalline glass, and therefore a disordered substance, and moves toward an ordered state by crystallization or, more precisely, perlitization (Friedman et al., 1997; Stevenson et al., 1998). This is accomplished by the absorption of water and a breaking of silicon and aluminum bonds, ultimately devitrifying the glass and forming perlite. As the process proceeds, an absorption front and hydration rim forms that theoretically occurs at a regular, linear rate through time. Measuring this rim with a petrographic microscope in microns theoretically yields an absolute date. On the surface, this would seem to be a remarkable method, resolving a number of dating issues in archaeological contexts in which organic datable material does not occur, but obsidian artifacts are abundant. More recently, the intervening negative effects of variable temperature and humidity through time have been found to influence the rate at which glass will hydrate. Due to this a number of researchers have rejected the method *in toto* (see Morgenstein et al., 1999; Ridding, 1996). Still, a number of researchers have continued to utilize the method, and it has a number of devoted followers, even in the face of discrepancies between radiocarbon dates and obsidian hydration dates in the same stratigraphic position. Stevenson, and others have attempted to derive intrinsic hydration models based on the premise that each single obsidian nodule contains a different proportion of water than any other, and this will produce ages compatible with other dating methods (see Stevenson et al., 1998). Most do agree that obsidian hydration is a useful relative dating method which can be used to determine the extent of mixing in a stratigraphic column; given the model, one expects to see larger rim measurements at the bottom of a site than at the top. If this is not the case, then stratigraphic mixing is indicated. Obsidian hydration holds great promise, but most archaeologists are hesitant to include it in the arsenal of absolute dating methods.

Abstract

Chronotype (morning-, neither-, evening-type) has been defined in the last decades as an individual difference variable highly relevant for both health and well-being. In the adult population, about 60% of the individuals are neither-type, while the extreme groups have 20% each. Chronotypes differ in their biological and performance circadian rhythmicity, with time differences between morning- and evening-types ranging from 2 to 12 h. Chronotypes also differ in personality traits, health habits, and prevalence of several psychiatric disorders. In general, being evening-type may be a risk factor, especially during adolescence.

Chronotype or circadian typology (i.e., morning-, neither-, or evening-type) has been defined in the last decades as an individual difference variable highly relevant for both health and well-being. The distribution in the adult population is of around 20% for each extreme group and the remaining 60% in the neither-type group. Chronotype groups differ in their circadian functions both in their biological parameters (e.g., sleep–wake, body temperature, melatonin, and cortisol) and in their cognitive performance (e.g., attention, memory, and executive functions), with morning-types showing an advance from 2 to 12 h in the acrophase or peak time when compared to evening-type individuals. The differences among chronotypes can also be seen in the personality traits, health habits, and prevalence of several psychiatric disorders. Neither-type individuals usually are in an intermediate position, although more studies are needed with this larger group to draw stronger conclusions. Being a morning-type may serve as a protective factor for several outcomes, while being evening-type may be a risk factor, especially during adolescence. Thus, chronotype should be taken into account both in health prevention and promotion programs and in therapeutic approaches.

Introduction

Chronotype or circadian typology is an individual difference construct that currently holds the interest of many research groups, since it plausibly provides a more robust explanation of differences in individual functioning than other subjective characteristics, such as extraversion. It has a special relevance in the circadian rhythmicity, which has a 24 h periodicity approximately, synchronized to the light–darkness cycle. The chronotypes (morning-, neither-, or evening-type) show clear phase mismatches in the majority of biological parameters and in cognitive performance.

Morning-type individuals show more synchronicity with the light–darkness cycle, and the peak times (acrophase) of their circadian functions appear earlier – advanced phase – than in evening-types. Thus, morning participants usually go to sleep and wake up earlier and their activity and performance peaks appear in the morning, while evening participants go to sleep and wake up later and their activity and performance peaks happen in the evening. The neither-type are usually in an intermediate position between both extreme groups and are the most prevalent adult chronotype, representing about 60% of the population. Each extreme group (morning- and evening-type) holds 20% of the adult population (Adan et al., 2012). Most of the research done so far has only included participants from the extreme groups, so more studies are needed on the neither-type, not only due to their interest in generalizing the results to the populations, but also to draw the circadian characteristics of the neither-type since their pattern may be mixed and not simply intermediate. That is, sometimes similar characteristics are observed to morning-type and others similar to evening-type.

The implications of chronotype in the academic and work environments, as well as in the clinical area, are very important. Although chronotype is an individual difference variable and belonging to an extreme group should not be considered pathological, currently it is acknowledged that the evening-type shows more difficulty in synchronizing to the social and work time demands usual in our society, as well as more risk of developing nonhealthy habits and suffering diverse psychopathological conditions. In spite of the data collected so far, we have a long road ahead so that health professionals and society in general become sensitive to the need to take into account the meaning of chronotype in both preventive and clinical areas.

Measurement of the Chronotype

Chronotype is usually assessed through self-assessment questionnaires, which take into account factors such as preferred wake-up time, level of activation after getting up, moment of the day when the participant feels best, and time of evening when they feel tired and need to sleep. The 19-item morningness–eveningness questionnaire (MEQ) is the most widely used and validated instrument (Horne and Östberg, 1976). There is also a 5-item short form (reduced morningness–eveningness questionnaire (rMEQ); Adan and Almirall, 1991) with acceptable psychometric properties that is especially useful in the context of large-scale survey administration. The data collection of the rMEQ was carried out in a sample that included a wider age range and a diverse number of occupational groups, and has been adapted in several countries.

Table 1 shows the rMEQ and the correction criterion for each of its items. It allows using an open-question format in the items that ask for specific time (items 1, 3, 4) so that the

Table 1 Reduced morningness–eveningness questionnaire (rMEQ). The correction criterion appears in parentheses

Please read carefully each question before answering and choose only one among the several options. Answer all the questions in order of presentation and with the maximum sincerity. Each question should be answered independently of the rest, without modifying the previous answers.

1. Considering only your own 'feeling beaten' rhythm, at what time would you get up if you were entirely free to plan your day?
   a. 05.00–06.30 h (5)
   b. 06.31–07.45 h (4)
   c. 07.46–09.45 h (3)
   d. 09.46–11.00 h (2)
   e. 11.01–12.00 h (1)
2. During the first half-hour after having woken in the morning, how tired do you feel?
   a. Very tired (1)
   b. Fairly tired (2)
   c. Fairly refreshed (3)
   d. Very refreshed (4)
3. At what time in the evening do you feel tired and, as a result, in need of sleep?
   a. 20.00–21.00 h (5)
   b. 21.01–22.15 h (4)
   c. 22.16–00.45 h (3)
   d. 00.46–02.00 h (2)
   e. 02:01–03.00 h (1)
4. At what time of day do you think that you reach your 'feeling best' peak?
   a. 05.00–08.00 h (5)
   b. 08.01–10.00 h (4)
   c. 10.01–17.00 h (3)
   d. 17.01–22.00 h (2)
   e. 22.01–04.00 h (1)
5. Usually there are two kinds of people, those who are more active during the morning and those more active during the afternoon/evening. Which one of the two adjusts best to your functioning?
   a. Definitely more active in the morning (6)
   b. Quite more active in the morning (4)
   c. Quite more active in the afternoon/evening (2)
   d. Definitely more active in the afternoon/evening (0)

Reproduced from Adan, A., Almirall, H., 1991. Horne and Östberg morningness-eveningness questionnaire: a reduced scale. Personality and Individual Differences 12, 241–253.

participant can reply with the preferred specific hour and minutes. The total score is obtained by adding the score for each item and the three chronotypes are obtained considering the following cut-off scores: evening-type <12, neither-type between 12 and 17, and morning-type >17. In some countries, such as Italy, slight differences have been determined for these cut-off scores. Table 2 summarizes the main rhythmic characteristics of the chronotype groups according to their answers to the rMEQ and other aspects related to their circadian rhythmic expression.

There are other questionnaires to assess chronotype individuals developed subsequent to Horne and Östberg, all with good levels of reliability and adequate validity (see Di Milia et al., 2013 for a review). We can mention the Composite Scale of Morningness (CSM), the Preference Scale (PS), and the Munich Chronotype Questionnaire (MCTQ), among the more established in this field.

Table 2 Main rhythmic characteristics of the three chronotypes. The marked times are derived from the intervals determined by the options in the reduced morningness–eveningness questionnaire (rMEQ)

Morning-type
- wake up early before 7.45 h, feeling very refreshed
- best time of day before 10.00 h
- go to bed by 22.15 h
- define themselves as clearly or more active in the morning
- high regularity of the sleep schedule in working and leisure days
- sleep–wake rhythm very similar to the light–darkness cycle
- more difficulty in adapting to shift work and jet-lag

Neither-type or intermediate-type
- wake up between 7.46–09.30 h, feeling quite refreshed
- best time of day between 10.00–16.00 h
- go to bed between 22.16–00.30 h
- define themselves as more active in the morning
- medium regularity of the sleep schedule in working and leisure days
- sleep–wake rhythm quite similar to the light–darkness cycle
- intermediate capacity for adaptation to shift work and jet-lag

Evening-type
- wake up later than 09.30 h, feeling quite or very tired
- best time of day from 16.00 h on
- go to bed later than 00.30 h
- define themselves as clearly more active in the afternoon/evening
- low regularity of their sleep schedule in working versus leisure days
- sleep–wake rhythm not very similar to the light–darkness cycle
- less difficult adaptation to shift work and jet-lag

Organization of the Circadian System

The chronotype is determined by a different organization of the endogenous biological clock, located in the suprachiasmatic nucleus (SCN) of the hypothalamus. Circadian rhythmic expression is entrained to the environmental light information and, especially, to the cycle of light–darkness, which is the main *zeitgeber* (time giver) of the biological clock. The information from the environmental light is transmitted to the SCN through the retinohypothalamic tract. In addition, a number of other cues have been identified including food, locomotor activity, and social cues. The SCN works closely with the pineal gland, which produces melatonin, the darkness signal in the organism. The endogenous clock is extremely precise in its functioning with the ability to adjust to environmental changes at the fastest possible speed (Rosenwasser, 2009). Figure 1 shows the organization of the circadian system. The differences among chronotypes have been interpreted as coming from the evening-type individuals having a lesser dependency on the environmental synchronizers with respect to the morning-type, and consequently on having a more powerful hypothalamic circadian control.

In the expression of the chronotype there are underlying genetic differences, but also environmental factors (Adan et al., 2012). The genetic basis may account for about 50% of the observed variability, and there have been found associations between the chronotype and polymorphisms of different clock-genes such as the *Period* and the *Clock* genes (Barclay et al., 2010; Ojeda et al., 2013). Among the environmental factors affecting chronotype, we should highlight the perinatal photoperiod to which the individual is exposed during the first months of life and also the light conditions due to the

Figure 1 Circadian system organization with the endogenous clock in the suprachiasmatic nucleus (SCN) of the hypothalamus and their coupling with the principal external cues (light–darkness cycle).

Figure 2 Differences in the peaks or acrophases of the circadian rhythmic functions of biological and cognitive performance markers between extreme chronotype groups (morning-type: ●; evening-type: ■).

longitude (east–west) and latitude (north–south) of the place of residence. The circadian organization of the individuals born within a short photoperiod (fall–winter) tends to be more morning-type, while that of those born within a long photoperiod (spring–summer) tends to be more evening-type. This is more clearly seen in men than in women. Although chronotype is a universal feature, depending on the country of residence, there appear differences in the observed distribution of the three chronotype groups. In a wide sense, we can state that there are more evening-type individuals as we move toward the west and the south.

Two key factors affecting the chronotype are age and sex (Adan et al., 2012; Randler, 2007). The morning chronotype is more frequent until age 10 and from age 50 on. Moreover, most of the studies hold that the tendency toward morningness increases with age. The age-related shift to morningness is observed after controlling for sociodemographic factors. During adolescence (12–17 years) there appears a pronounced tendency to eveningness and its decrease may be considered as a biological marker for the end of adolescence (Roenneberg et al., 2007). The population studies also find a higher evening-type prevalence in boys and men, and a higher morning-type in girls and women. The sex differences disappear following menopause in women, so it is hypothesized that such differences may be explained by the circamensual rhythmicity associated with the menstrual cycle.

Biological Circadian Rhythms

There are several outputs with circadian rhythmicity (biochemical, physiological, behavioral), and the most obvious one is the sleep–wake cycle. Among these, some are considered to be markers of the functionality of the circadian system, thanks to their robustness and implications in both health and well-being, mainly body temperature and the melatonin and cortisol hormones. In all the cases there are differences among chronotypes although depending on the parameter they are of a higher or lesser magnitude (see Figure 2).

Evening-type individuals go to sleep and wake up 2–3 h later than the morning-type, although there are no differences in the total amount of sleep if the individuals are free to choose when to sleep. The sleep–wake rhythm in the morning-type is very similar to the light–darkness cycle, while in the evening-type it shows a delay. Polysomnographic results (sleep quality) show longer sleep latency and delayed appearance of the first REM episode in evening individuals, who also overestimate the latency to fall asleep with subjective assessments. If the evening-types have to wake up early in the morning, they show more difficulties to fall asleep and a shorter sleeping time, together with higher day-somnolence levels and a stronger need to take a nap during the day. Thus, during the working days these individuals accumulate sleep privation and try to compensate for it during nonworking days, usually during the weekend, in which the time devoted to sleep increases and is delayed according to the hourly preference. This phenomenon has been termed 'social jet-lag' (Roenneberg et al., 2007). In contrast, the sleep times of morning-type individuals are more stable or rigid, without significant differences between working and nonworking days. This may be of advantage in environmentally stable schedule conditions but makes it harder to adapt to environmental schedule changes, such as working shifts and jet-lag situations.

Evening-types present a higher level of wrong beliefs and a lesser knowledge and practice of sleep hygiene, whereas morning-types show a more correct level of beliefs and practice of sleep hygiene. Being evening-type is a risk factor to develop a delayed-phase sleep syndrome, especially during adolescence of early adulthood as well as insomnia in adulthood. In contrast, being morning-type is a risk factor to present an advanced-phase sleep syndrome in the last decades of life.

Body temperature has a sinusoidal function whose maximum peak appears between 17 and 20 h and its minimum between 3 and 5 h in the morning. It is considered an estimator of brain activity and its disorganization is well known in several mood disorders, especially in endogenous depression. Morning-type individuals show an earlier circadian temperature phase around 2 h and have a lower amplitude than evening-types.

The melatonin hormone is considered to be the best marker of the endogenous circadian pacemaker. Melatonin presents a secretion with a marked night peak dependent on the duration of the environmental photoperiod, and with minimum values

during the wake period. It is essential to start and keep sleep as well as to produce an acceptable sleep quality (physical and psychological recuperation). Morning-type individuals present an advance in their melatonin peak of approximately 3 h with respect to the evening-type, without differences in amplitude. Cortisol circadian rhythm is characterized by a marked secretion peak near the time of awakening, associated to preparing for the diurnal activity, and a minimum peak during the first half of sleep. The morning-types present an advance of the cortisol peak of about 1 h and higher levels immediately after awakening in comparison to the evening-type.

Cognitive Performance Rhythms

Chronotypes show remarkable differences in the optimum execution moments (acrophase) in cognitive tasks (see Figure 2). Although there are no differences in cognitive performance among chronotypes when evaluated at their optimal times of day, the evening-types are in worse activation conditions during the conventional school or work time periods. We will classify the tasks depending on whether the execution is focused on attention, memory, or executive functions, since these present a diurnal evolution and clearly differentiated acrophases (Schmidt et al., 2007; Valdez et al., 2008).

Attention Tasks

We regard attention tasks as repetitive and monotonous tasks that involve perceptual and motor skills, and whose common characteristic is to prioritize reaction time. Among these we distinguish those based on surveillance and manual dexterity since they present different temporal patterns of execution.

In surveillance tasks, execution speed in the early hours is low and increases along the day, peaking at 19.00–21.00 h, while precision is higher in the early hours (08.00–10.00 h) decreasing along the day. The extreme chronotypes differ in the speed precision of these tasks with phase mismatches of around 7–12 h. The diurnal function for tasks of manual dexterity presents the best executions around midday (12.00–14.00 h), and neither the preceding increase nor the following decrease are so marked as in the surveillance tasks. However, this is the evolution in the morning- and neither-type groups, while for the evening-type the peak of performance happens in the evening (18.00–20.00 h).

Memory and Executive Functions Tasks

Memory tasks involve the presentation of a material that the participant must recall after a certain amount of time, or use it to reply to an exercise that he is presented, or freely narrate its content. These tasks are differentiated according to the capacity and duration of information storage. For the immediate or short-term memory tasks, the interval between presentation–retrieval is short, and the capacity of storage is limited (e.g., retrieving lists of digits or words). The optimal moment of execution is during the first hours of the morning (08.00–11.00 h) for the morning-type, while for the neither-type it happens during midday, and for the evening-type during the afternoon.

Working memory tasks require a longer duration of the information storage and a limited but larger capacity than in the short-term tasks (arithmetic, verbal reasoning, and comprehension). They present a diurnal evolution, in relation to the speed of increase in the morning until they reach their peak at midday (12.00–14.00 h), and then decrease significantly until the last hours of the day. In contrast, precision is superior in the first hours of the morning (09.00–11.00 h). In all the cases, the phase mismatches are observed among the groups, with optimal schedule advances in morning-types with respect to evening-types from 2 to 7 h.

Long-term memory tasks have intervals between presentation and retrieval ranging from several hours to days or even months. The duration of the storage of the information is long and of unlimited capacity, and the material is better remembered if it has been presented toward the end of the afternoon (18.00–20.00 h). This normative pattern is applicable to the neither-type, while it appears during the first hours of the afternoon if they are morning-type and during the first hours of the evening if they are evening-type.

There are fewer works assessing the differences among chronotypes in more complex cognitive tasks, such as executive function tasks. Executive functions include the initiative, inhibition, flexibility, planning, prevision, self-monitoring, verification, and correction components, which may modulate the performance of all tasks requiring decision-making or problem solving. The diurnal functions of executive functions have not been modeled yet, since it is harder to obtain repeated measures with these tasks. However, it can be stated that they meet the synchrony effect. This is, individuals who are more alert in the morning (morning-type) tend to perform better in the morning than in the afternoon/evening and the opposite in the case of individuals who are more alert in the afternoon/evening (evening-type).

The study of the possible relationship between chronotype and the academic outcomes in children, teenagers, and college students is of undoubted interest. In all cases advantage of the morning-type compared to evening-type was observed. Both the attention in class as academic achievement and grading are better in morning-type students (Preckel et al., 2011, 2013; Vollmer et al., 2013).

An interesting approach is to consider the cognitive style, understood as the preferred way of information processing (Adan et al., 2012). It has been observed that morning-type is associated with the left-thinking style and evening-type is associated with the right-thinking style (Fabbri et al., 2007). The left-thinker follows an analytic and sequential mode of reasoning and relies preferably on verbal–abstract representation, while the right-thinker tends to process information in an intuitive, holistic, gestalt-type, synthesized, and visual–motor way. Future research should look deeper into this approach, which will certainly produce interesting theoretical and applied data.

Personality Characteristics

With respect to personality traits, several works have found important associations with the scores in morningness–eveningness or with the chronotypes (Adan et al., 2012;

Tsaousis, 2010). Although none of these relations is in itself a disorder, it is true that all of them together in extreme cases may constitute risk factors for the appearance of several dysfunctional behaviors and mental disorders.

For the dimensions in the model proposed by Eysenck, there is a tendency in morning-type individuals to score toward the introversion pole, while the evening-types score toward the extraversion pole. Using the Big Five Model of personality (extraversion, agreeableness, conscientiousness, neuroticism, and openness), proposed by Costa and McCrae, most studies reported a strong positive association between morningness and conscientiousness and, to a lesser extent, with agreeableness. The observation that morning-types were more conscientious and higher in self-esteem than the evening-types suggest that conscientiousness rather than the extraversion dimension may be the personality factor that best distinguishes chronotypes. The association with the neuroticism constructs or anxiety trait is less obvious, although some works obtain higher scores in the evening-type participants.

More recently, using personality models with a biological basis, such as Cloninger's and Zuckerman's, has provided new and revealing associations for both adolescents and adults. The evening-type participants present higher scores in impulsivity and novelty seeking in comparison with the morning- and neither-types. In contrast, the morning-type showed higher scores in harm avoidance, persistence, self-directedness, cooperation, and activity.

Moreover, more data have been collected using different standardized questionnaires. With the Millon Inventory of Personality Types it has been observed that the morning-types prefer to obtain information from their surroundings based on concrete sources and direct experience, whereas evening-types prefer information based on intangible and abstract data. In addition, evening-types interpret the information using subjective and emotional parameters and tend to elaborate it with knowledge schemata that are newer and more original. The evening-types also express less affinity in their relationships with other people (acquiescence) and less respect for customs and social norms. Recently a more appropriate emotional intelligence pattern (Antúnez et al., 2013) and adaptive emotional profile with higher control, inhibition, and coping (Ottoni et al., 2012) has been observed in the morning-type than in the evening- and neither-types.

Mental Disorders

Mood Disorders

The chronotype is involved in both the prevalence and course of several mood disorders in which the impairment or even loss of the circadian rhythmicity is common. Most of the works in this area have found a higher prevalence of seasonal mood disorder and major depression in evening-type participants, as well as a more severe depressive symptomatology and suicidal ideation (Merikanto et al., 2013). Bipolar disorder is also more prevalent among evening-types, especially in type II. In all cases, remission and asymptomatic periods are associated to a proper reorganization and maintenance of the circadian rhythmicity.

Eating Disorders

When there is no pathology, morning-type participants tend to have their meals in more regular schedules and usually follow healthier diets. The evening-types, in addition to having more variable time patterns, also tend to 'snack' between meals and express a lesser preference to follow a 'Mediterranean' diet and to control the use of normal and spicy seasonings. The available data point at an increased risk for the morning-types to develop eating restrictions and anorexia nervosa, while the evening-types tend to present uncontrolled eating habits, with more perceived hunger and higher body mass index (a common behavior in bulimia). There is a higher proportion of evening-types among the patients diagnosed with bulimia, and remission of the symptoms shows a direct association with decrease of eveningness (Natale et al., 2008).

Drug Use and Dependency

Research by Adan (1994) observed a higher use of legal drugs (alcohol, caffeine, and nicotine) in evening-types when compared to the morning- and neither-types. Since then, several other works have confirmed the same pattern in different countries and with varied samples. Among them we highlight the study by Prat and Adan (2011), which found that the evening-type participants also consume more illegal drugs (e.g., cannabis, ecstasy, and cocaine), have more problems related to alcohol consumption and more severe hangover symptoms (learning problems, tiredness, headaches, sensorial hypersensitive, irritability, and thirst) than the morning-types. **Figure 3** shows the percentage of participants who consume different drugs, classified according to their chronotype.

In drug-dependent participants, the most studied drugs are alcohol and tobacco. These participants present flatter circadian rhythm functions and phase delays, which are related to the

Figure 3 Percentage of drug-consuming participants according to chronotype (morning-, neither-, and evening-type). For the legal drugs excluding alcohol, the habitual consumption has been considered, while for the illegal ones the occasional intake has been taken into account, since it is much less frequent. * Hazardous alcohol use, defined as a pattern of consumption that places at risk for adverse health events (for the sample corresponds to binge drinking pattern). Data revised from the study by Prat, G., Adan, A., 2011. Influence of circadian typology on drug consume, hazardous alcohol use and hangover symptoms. Chronobiology International 28, 248–257.

degree of dependency. In severe cases, the circadian rhythmic expression may even disappear. During the processes of detoxication and dehabituation it is convenient to take into account the rhythmic alterations, since their resolution is associated to the maintenance of abstinence.

Other Disorders

It has been reported that adults suspected of having attention deficit/hyperactivity disorder tend to be in the evening-type (Voinescu et al., 2012), and that this relationship is stronger for the inattention factor than the impulsive hyperactive factor. There is also evidence of the association between the evening-types and higher levels of anxiety symptoms (Hsu et al., 2012), this being more present in the first hours of the day.

Adjusting the Clock: Preventive and Therapeutic Strategies

Preventive and therapeutic approaches should take into account the circadian rhythmic organization of the individuals, with special emphasis on redirecting the time patterns toward a better synchronization with the light–darkness cycle. This is more important in the more vulnerable periods of life, such as adolescence and old age: in adolescence in order to avoid the extreme evening-type pattern, and in old age in order to avoid the extreme morning-type pattern. Chronobiological strategies – regular time patterns, light therapy, and melatonin administration – are effective in several situations and have been proven to be secure even in special populations (Adan, 2013).

In many cases it may suffice to establish regular time patterns of wake–sleep, meals, and daily physical and social activity with a tendency toward a morningness pattern of functioning. Exposition to morning light or light therapy may be considered when scheduled habits alone are not enough to reorganize circadian rhythmic expression. The scientific evidence available on the nonvisual beneficial effects of light is unquestionable. Light therapy stimulates the pineal gland to synthesize an adequate peak of night melatonin for a better sleep–wake cycle tuned to the environmental signals. In areas with an adequate environmental light, it is recommended to get exposure to natural daylight from half an hour to 2 h daily, preferably in the morning. When exposition to natural light is not possible or becomes insufficient, bright light therapy may be used instead. This consists in the exposition to artificial light of total spectrum at an intensity of 10 000 lux, with a standard prescription of application of at least 30 min daily. Finally, the administration of exogenous melatonin at the end of the day is another possibility to consider in order to favor the proper expression and organization of the circadian system.

Abstract

Religion has manifold and differing political functions for different societies. These functions underlie and influence the relationships between religious institutions and the state on the level of the law; their role in history often forms an important part of the collective memory of a people and their identities. Today, it remains a foremost challenge to politics and international law to institutionalize universal foundational claims of freedom of religion or belief and equal treatment in the large variety of differing cultural contexts. While it is possible to identify three basic types of relationships between religions and the state – state religions, separation regimes, and cooperationist systems – these classifications are overlaid by social circumstances which suggest different groupings. Contemporary challenges often relate to migration, state aid to religions, religious autonomy, and pluralism.

Terminology

The term Church and State usually represents the relationships between religious organizations or authorities on the one hand and secular government on the other. Within political science it sometimes also stands, in a somewhat broader approach, for the relationships between religious organizations or authorities with the polity. In this sense, political parties and relevant actors of civil society come into the focus.

In the course of globalization and increasing sensitivity for cultural respect, the term has been questioned as discriminatory against non-Christian beliefs. Church is a genuinely Christian institution not used within the theological context of most other religions, although the Buddhist sangha is sometimes thought to share some features. In the other monotheistic religions, such as Islam and Judaism, and in Hinduism the status of religious authorities and their relation to secular political authority suggest quite different patterns from those typical of areas based in Christian traditions.

Furthermore, it has become quite common in public discourse, not to distinguish between churches and sects or cults, as these latter terms carry for many a somewhat pejorative connotation.

In order to avoid possible sensitivities it has been suggested to use the term Religion and State instead of Church and State. This also takes up the idea that in view of their relations to secular powers, religious institutions and authorities are based in the religious life of individuals. The idea of individual freedom of religion as a concept of human rights forms a basis of this approach; at least, the term Religion and State includes an individual aspect of religion which is less obvious in the more institutional, collective, or corporative approach visible in the term Church and State.

Asking for the relationships between religion and the state (or church and state) implies a general distinction or even a divide between the sacred, for which religion stands, and the secular, identified with the state. This again is a rather modern interpretation based primarily in Christian teaching, referring to the parable as to which one should render unto the emperor the things which are the emperor's and unto God the things that are God's.

Religion–state relationships have come into the focus of political science within recent decades; they have been a subject for legal scholarly work for long. Sociology looks at them primarily from the perspective of religious demography; they have also come to the attention of economists, mostly in regard of financing of religion and in view of religious rules on a proper economy. From the perspective of religions themselves, the relationships between religion and the state is an important matter of theology; their approaches range from promoting intense and direct intervention into the secular sphere to complete abstinence.

Functions of Religions

The relations between religions and states across the world are remarkably diverse. They reflect, among numerous other factors, differences of culture, history, religious demography, constitutional systems, and political circumstances. While it is often suggested that there should be one ideal system of religion–state relationships implemented throughout all states, others insist that the specific patterns of such relationships should be framed according to the diverse needs of the individual states. Differences often even occur between regions within the same state, reflecting developments in history or religious demography. This is the case in France, where in general a far-reaching separation between the state and religious organizations is promoted, while in the eastern parts of the country several religious organizations have a special public law status, receive direct financial support from the state, Christian religious symbols are depicted in public buildings, and the president of the republic appoints the Roman-Catholic bishops of the dioceses of Strasbourg and Metz; in some other parts of France again, different specific rules apply. Likewise, in the United Kingdom, the Anglican Church is the established church in England, but disestablished in Wales, while in Scotland the Calvinist Church of Scotland is the national church, and special regimes apply in several other parts of the

country. In Greece, Islamic law applies for the Muslim minority in Western Thrace. Such circumstances reflect the importance attached to religious needs, history, and cultural differences.

Religion has manifold and differing political functions for different societies. These functions underlie and influence the relationships between religious institutions and the state on the level of the law; their role in history often forms an important part of the collective memory of a people and their identities. Individual freedom of religion is a strong factor of national identity of the US. In China, autonomy of religions is often regarded as a threat to the unity of the country. In Tibet, the Dalai Lama represents for many the idea of a politically independent state. Islam provides a centerpiece of identity for countries of Muslim tradition in defining themselves against what is regarded as 'the West.' Israel defines itself in its Declaration of Independence as a Jewish state. Roman Catholicism is a key factor of national identity in Poland; the Roman Catholic religion and its institutional structures had held together the Polish people in the many partitions of the country between Christian Orthodox Russia and Protestant Prussia; it maintained this identity-providing function also in the times of communist rule and proved to be a decisive factor in regaining independence in the collapse of the Soviet Union to which it contributed. Protestantism emerged as a main factor in forming nation-states in Europe; the Protestant faith remained intrinsically intertwined with the monarchies in Scandinavia, the United Kingdom, the Netherlands, Switzerland, and parts of Germany. Central Europe has experienced 100 years of devastating wars between Protestants and Catholics in the sixteenth and seventeenth centuries. Religious wars culminated in the 30 Years War (1618–48) in Germany, the Huguenots War (1562–98) in France, and to some extent the British civil wars (1642–51). These historic events still form part of the collective memories of the relevant countries and influence the law until today.

Establishment and disestablishment of churches in the United Kingdom mirror self-consciousness and survival of national identities within the country. The synod of the Calvinist Church of Scotland proved to be the center of Scottish political self-identity for lack of a Scottish parliament since the Act of Union in 1707; only in 1999, a Scottish parliament was recreated.

For Ireland, the Roman Catholic denomination was a foremost factor of identity and resistance against the English rule over the country in the nineteenth and early twentieth centuries. Religious affiliations are still relevant within the political antagonisms as well as peace-building attempts in Northern Ireland.

In 1789 in France, the idea of 'la République' together with the principle of 'laïcité' carried a specific identity in promoting a distinct ethos and set of values that is hesitant if not hostile in relation to religion. It emerged in the fight against an overwhelmingly powerful Roman Catholic Church before the 1789 French Revolution and in the course of the nineteenth century.

In Christian Orthodox countries, Orthodox religion often serves as an ideological glue of the society and statehood. The existence of an autocephalous or at least distinct Orthodox Church underlines the independence of the country. It also is of dominant impact in the Russian Orthodox Church filling in the ideological vacuum after the collapse of communist ideology in Russia. In Greece, the Greek Orthodox Church preserved identity of the Greek people against Turkish Ottoman rule over centuries. Somewhat similar, in Serbia, the Orthodox Church as something like a state church in the Muslim Ottoman Empire protected Serbian identity.

The long list of political functions of religion in history and presence underlines that religion is not only a question of individual belief; religion always has a very public, political function for group and national identities and survival. Often times, people turn to the religious sphere and their institutions when they do not find political representation in the secular sphere.

The functions of religion are of ongoing impact. It is relatively easy to separate the state from religious institutions. Moreover, the state can refrain from identifying with a specific set of religious teaching. It is, however, probably impossible for the state to completely separate from religious ideas and traditions: Days of rest such as the Sunday, legal institutions such as matrimony, or basic assumptions such as human dignity are deeply entrenched in religious convictions. Protecting them (and not the holy days, institutions, or fundamental assumptions of other religions) by secular law may well mean some degree of identification; disregarding them is also taking sides and implies negative identification. Democracy entails that the individual can vote on secular issues by reasons of his or her individual religious beliefs; by this way religious convictions will influence the state. While some demand that state decisions should be taken completely independently from religious reasoning and that for every such decision there must be a secular reason, this would amount to an antireligious discrimination, and would probably be impossible, anyway.

Human Rights and Institutional Approaches

A large number of international instruments have taken up the relevance of religion for individuals as well as for the public sphere.

These international instruments mostly promote the idea of human rights. In view of the relationships between state and religious institutions, they, thus, contribute to a development that shifts the basis of these relationships from an institutional approach to an individual human rights approach. Today, a predominant point of reference for the relationships between state and religion is formed by the right to freedom of religion or belief as stated in Art. 18 of the 1948 UN-Universal Declaration of Human Rights: "Everyone has the right to freedom of thought, conscience and religion; this right includes freedom to change his religion or belief, and freedom, either alone or in community with others and in public or private, to manifest his religion or belief in teaching, practice, worship and observance."

Beyond the question of freedom of religion or belief, the issue of equal treatment of religions has become prominent in the field of religion–state relationships. While some claim identical treatment of all religions, others insist on respecting differences based in factors such as tradition, demographic facts, or social and cultural impact of the various religions.

It remains a foremost challenge to politics and international law to institutionalize universal foundational claims of

freedom of religion or belief and equal treatment in the large variety of differing cultural contexts.

Typology of Systems

It is possible to identify three basic types of relationships between religions and the state. The first basic type is characterized by the existence of a state religion or predominant religion. In this system, there are close links between state power and the existence of religious institutions. The systems of England, Denmark, Greece, Malta, and Finland belong to this basic category. On the other hand, there are systems founded on the idea of a strict separation of state and religious organizations, for instance, in the US, in France, with the exception of the three eastern départements and some other regions, and also in the Netherlands. There is to a great extent a legal separation in Ireland also. The third type features the basic separation of state and religions while simultaneously recognizing a multitude of common tasks, in the fulfillment of which state and religious organizations activity are linked: Belgium, Poland, Spain, Italy, Hungary, Austria, the Baltic States, and Portugal belong to this group. While the Australian constitution states – similar to the First Amendment to the United States Constitution – that the Commonwealth shall not make any law for establishing any religion, this has been interpreted as allowing for public funding of religious institutions and for closely cooperating with them. Also, the pattern of 'symphonía,' signifying an intense relationship of loyalty between the state and the church traditionally established in countries of Christian Orthodox tradition, figures mostly in the cooperationist approach.

These classifications according to legal and theoretical considerations are instantly overlaid and rendered questionable by social circumstances which suggest different groupings. The religious influence on the state in mainly Catholic Ireland is probably stronger and more direct than the wording of the constitutional provisions suggests. In the same way, there would be a closer similarity in the social relevance of religion as between Greece, Spain, and Italy than would be revealed in a comparison of Greece with Denmark or the United Kingdom. Likewise, it has been suggested that a 'civic religion' strongly influences US politics.

In some states, agreements between state and religious communities play an important role; in the context of the Roman-Catholic church the most important of those treaties, the concordats, have the status of international law treaties. Several states also conclude treaties with religious organizations as a matter of state law in order to meet the specific individual needs of the religions concerned and to regulate matters of common interest. Therefore, some speak of states with a covenantal system of the relations between state and religious organizations as a special category. However, the impact of such agreements must not be overestimated, important as they are; it seems that they mirror a system of cooperation rather than they would establish it.

A further refined classification of relationships between state and religions that looks from the viewpoint of freedom of religion or belief distinguishes between a large number of typical settings: theocratic states, in which the linkage between state and religion is so close that it is virtually impossible to distinguish state from religious rule; established religions systems in which there is an official state religion; religious status systems where the state recognizes the jurisdiction of a number of religious systems, typically in areas dealing with family law and inheritance; endorsed religions in which the state affirms that a particular religion has a special place in the country's history, culture, and tradition; preferred sets of religions in which multiple religions are favored; cooperationist systems distinguished by the fact that they take a neutral but positive and 'cooperative' stance toward religions in society, typically in fields such as religious education, various humanitarian services, or church finance; accommodationist regimes, accommodationism thought of as cooperation without any direct financial subsidies; separation regimes, covering a wide and diverse range of approaches from protecting religion from the state to protecting the state and society from excessive religious power; the approach of laïcité preferring a rigid separation; secular control regimes which try to exercise strict control over and minimize the influence of religious institutions; and finally abolitionist states in which the secular authorities aim at elimination religion altogether.

The relationships between states and religions are in constant flux. There seems to be a strong tendency to increasingly favor Islam in states with a Muslim tradition by establishing the sharia as the centerpiece of the legal system. In a situation of revolution and civil unrest, religiously inspired groups try to or succeed in taking over state power. In European states, a convergence of systems is predominant leading to a general regime of cooperation between states and religions. In some countries, the earlier antichurch and anticlerical attitudes faded as the centuries passed and their legal consequences are being gradually reduced. Religious communities are allowed greater freedom, and the conditions for meeting religious needs are created by the state. On the other hand, there are clear moves toward the disestablishment of the established churches; thus, Sweden has to a very large extent cut the formerly close ties between the state and the Lutheran Church, and reforming the previous state church systems is a general tendency in the Scandinavian countries.

In the US, emphasis is laid at least recently by the Supreme Court on acknowledging the right of autonomy of religious organizations. Such autonomy is also underlined by the European Court of Human Rights in interpreting the guarantee of freedom of religion or belief as stated in the European Convention of Human Rights, when the court insists that the autonomous existence of religious communities is indispensable for pluralism in a democratic society and is thus an issue at the very heart of the protection which freedom of religion or belief affords.

In many parts of the world, the state supports one or several religious organizations while discriminating against others. A foremost instrument in doing this is a system of registration of religious communities that imposes barriers for specific religions, mostly small or new ones.

Ancient or archaic religiopolitical systems are often understood to combine religious and political functions within a single structure of authority. Divine kingship or theocratic rule can be seen in many cultures, such as in the Roman Empire, when the emperors assumed a godly or godlike status.

Religious functions, however, were from early times usually distinct from functions of secular power.

Religious Approaches

In Christian cultures, the church was from early on conceived as a distinct institution. However, rulers often asserted over the church some sort of sacral or at least political authority, while popes or patriarchs claimed supreme authority also over the secular rulers. Numerous theories provided explanations for manifold approaches such as the medieval theory of the two swords dating back to the Pope Gelasius I, the two kingdoms doctrine based in the Protestant theology of Martin Luther, or the divine-right theory of kingship which assumed sovereignty of the monarch directly held by the grace of god; the Byzantine emperor Justinian I provided a classical description of the concept of symphonia strongly held in Eastern Orthodox Christian theological and political thinking, which claims that church and state are to be complementary and exhibit mutual respect.

Within cultures based in Islam, religious, and secular authority remained even more closely linked. It has been argued that this was because Medina under Muhammad was considered to provide a perfect model for the life of the community of believers. Within this view, the Prophet himself recognized the sovereignty of God alone, and, accordingly, it has not been open to his successors to claim sovereign authority in their own right; rather, it has been the duty of all who exercise authority on behalf of the community faithfully to implement the rules encapsulated in the Qur'an and the traditions of the Prophet as interpreted by legal scholars.

This interpretation sees parallels within Judaism, where the authority of divine law, as interpreted by rabbinical scholars, was held to be supreme.

In a historical perspective, differences between the world religions in their approaches to the relationships between the institutions of secular and sacral powers, while existing, seem to be less prominent than is often assumed. The different approaches to the status of religion vis-à-vis the secular sphere and its authorities seem to surface in any of the world religions from time to time according to the larger political circumstances of the time. Recently, the reassertion of theocratic claims has gained much support in different parts of the world.

Contemporary Challenges

Contemporary challenges to a large extent relate to the developments within states with a Muslim background and culture. Political unrest and revolutionary movements demand and often achieve to implement religious rules in the legal and social systems. Violent confrontation, terrorism, and military conflict are embedded in religious convictions. While this often leads to intense limitations of freedom of religion, the community building and peacemaking power of religion are only gradually perceived.

Migration, mostly also, but in no way exclusively, of Muslim background, challenges the traditional systems of religion–state relationships in many countries, as the newcomers call for equal treatment and accommodation of their religious needs and traditions. This often requires changes in deeply rooted traditions within the receiving society as well as among the newcomers. Points of conflict arise in many social and legal fields such as family and inheritance rules, food requirements, days of rest, burial norms, garment traditions, the construction of religious buildings, or the legitimacy of religious courts competing with state jurisdiction.

In some parts of the world, such as in Europe, former excitement about new and small religions has softened, while in others, such as in Asia, they are still seen as a matter of concern.

Involvement of religious organizations in matters of what is seen as secular politics is often regarded with skepticism or even complete rejection. While in some religious perspectives, such political involvement is seen as a necessary expression of religious activity and freedom of religion or belief, others regard it as an impermissible intrusion of religion into the secular sector.

The education of the young generation is a constant and predominant field of special attention in the relationships between religious organizations and the state. While many states allow for and even support educational institutions maintained by religious organizations, others try to suppress all religious influence on education. The systems of specific religious instruction in state run schools vary considerably. In some states there is complete absence of such instruction, others provide information on various religions, and in many states confessional teaching takes place usually conducted by the individual religions themselves.

Some states, like the US, are very reluctant to afford financial support to religious organizations. In these systems, religious organizations depend on their own assets or private donations. Most other jurisdictions have introduced systems of direct state financial aid to religions. A common feature is providing tax exemptions for religious organizations. In a number of regimes, religious organizations can participate in the state taxation system by having a part of the state income tax assigned to religious or charitable organizations such as Italy, Spain, and Hungary. In some states, religious organizations have the right to levy own taxes on their members such as in Germany, Austria, and Sweden or in a number of Swiss cantons; such church tax is not a state tax that favors certain religions, but the qualified religious organization itself is entitled to impose the tax. Usually, more than one of these approaches can be found in combination with one another. While some regard state financing of religions as a violation of separation between state and religious organizations, others insist that the state renders financial aid to many a group and must not exclude religious organizations, because otherwise the state would discriminate against religion. Critics of mere donation models often claim that this approach allows an undue influence on the religious organization by individual big donors.

A matter of political and legal controversy is often the status of religious and other personnel of religious organizations. Many religions throughout the world operate hospitals and homes, kindergartens, schools, or universities, and they maintain farms and economic enterprises. In doing so, religious organizations are in many cases large and powerful employers. Mostly, religious personnel such as priests, ministers, or members of religious orders who provide services for their

community enjoy a special status as their relation to the religious organization is not primarily regarded as an employment, but as a fundamentally spiritual relationship that requires special rules. Many jurisdictions, such as the US and most European countries, also provide for special regimes in the labor law that applies for religiously oriented institutions and which pays attention to their specific ethos. Usually, employees are expected to respect specific loyalty obligations to their employer which would often not or in a different shape apply in nonreligious institutions.

In such contexts, religious organizations contribute to a fundamental pluralism. They often offer alternatives in a life that is otherwise completely controlled by secular institutions and powers. While increasing antagonisms between competing religious groups in many parts of the world are seen as one of the predominant contemporary challenges, freedom of religion or belief can be endangered. On the other hand, freedom of religion or belief is often seen as one of the foundations of a democratic society. It is regarded as one of the most vital elements that go to make up the identity of believers and their conception of life, but also a precious asset for atheists, agnostics, skeptics, and the unconcerned. The pluralism indissociable from a democratic society, which has been dearly won over the centuries, depends in this view on it. It is mostly assumed that the state has legitimate regulatory power in this sphere and in its relations with the various religions, denominations, and beliefs. International instruments and many national jurisdictions hold that the state has a duty to remain neutral and impartial in exercising this regulatory power. Especially, when different religious groups come into conflict with each other, the preservation of pluralism and the proper functioning of democracy are seen to be at stake, one of the principle characteristics of which is held to be the possibility they offer of resolving a country's problems through dialogue, without recourse to violence, even when they are irksome. Accordingly, the role of the authorities in such circumstances is seen not to remove the cause of tension by eliminating pluralism, but to ensure that the competing groups tolerate each other.

Cities and the Financial Crisis

Abstract

There is a long history in social science that connects urbanization to capitalism. This article discusses how the work of Manuel Castells and in particular David Harvey informs our understanding of the urbanization of financial crises in the United States and elsewhere. The concepts of capital switching and financialization are central to the argument presented here. The article also includes a discussion of the management of the crisis, focusing on both the failed institutional response to the financial crisis and the global and local grassroots responses to the financial crisis.

Introduction

There is a long history in social science that connects urbanization to capitalism. Perhaps two of the most prominent contributions to this nexus are to be found in the earlier work of sociologist Manuel Castells (1977, 1983) and both the early and contemporary work of human geographer David Harvey (1982, 1985, 2010), but it can also be found in older works such as Friedrich Engels's *The Condition of the Working Class in England* (1844/1999). For these and other authors, urbanization is a necessary condition for capitalist expansion. Another necessary condition of capitalism, according to the same authors, is that capitalism creates its own crises.

To Harvey, one fundamental contradiction in capitalism is that individual capitalists act in a way that, when aggregated, runs counter to their own class interests. This results in overaccumulation and, in time, a variety of crises. The early signs of crisis often include an overproduction of commodities, falling rates of profit, surplus capital (e.g., money capital lacking opportunities for profitable employment), and surplus labor or a rising rate of exploitation of labor. Harvey then distinguishes different kinds of crises: a partial crisis, which affects a particular sector, place, or set of mediating institutions; a switching crisis, which involves a major restructuring of capital flows either between sectors of the economy or between places; and a global crisis, which affects most sectors of the economy and most places within the capitalist system.

The financial crisis that started in 2007–08 and continues to drag on and mutate in various ways and places can be characterized as a global crisis since it affects most sectors of the economy and most places around the world (Aalbers, 2009). The fact that one can mention sectors or places that are not affected much by the crisis should not be seen as proof that this is not a global crisis. It is merely proof that some sectors and places have not yet been fully integrated into the global capitalist system or that they are seen as safe havens to switch investment to. This is 'only' the third global crisis of capitalism, following the one of the 1930s (with the Second World War as its aftermath) and the one that became most visible after 1973 but had been building throughout the 1960s.

The current global crisis had been building throughout the 1990s and early 2000s. Its earlier manifestations could be seen in more localized events such as the first subprime crisis in the late 1990s in the United States, the late 1990s Asian and Russian financial crises, the Argentine crisis at the dawn of the new millennium, and the explosion of the dot-com bubble in the early 2000s. These were all partial crises or switching crises because they hit only certain places or certain sectors of the economy and resulted in money capital being switched to different sectors and different places. Two sectors in particular became the main destinations for money capital to flow out of sectors and places in crisis: real estate and finance itself.

David Harvey: Capital Switching

In Harveyian terms, real estate is seen as an asset in which money can be invested and disinvested by directing capital to the highest and best uses, and by withdrawing and subsequently redirecting capital from low payoffs to potentially higher ones. Capital switching entails the flow of capital from the primary circuit (the production, manufacturing, and industrial sectors) to the secondary circuit, which includes real estate and infrastructure. (Harvey also identifies a tertiary circuit, the circuit of social infrastructure, which is identified as investment in technology, science, conditions of employees, health, and education.) Switching from the primary to the secondary circuit takes place when there is a surplus of capital in the primary circuit and signs of overaccumulation emerge. Capital switching is a strategy to prevent a crisis, but because of the inherent contradictions of capitalism, investment in the secondary circuit will only delay, not take away, the crisis. In empirical terms, the decline in production growth in many Organization for Economic Co-operation and Development (OECD) countries, the overaccumulation in oil-rich countries, the savings glut in countries like China, and the implosion of the dot-com bubble all resulted in capital switching into the real estate sector.

Building on David Harvey's theory, I have argued elsewhere (Aalbers, 2008) that the early 2000s may have seen the rise of capital switching to what I call the quaternary circuit of capital, where the financial sector is not at work to finance production (first circuit), real estate (second circuit), or the building up of welfare states (tertiary circuit), but simply the growth of money capital through finance. Financialization can be characterized as capital switching from the primary, secondary, or tertiary circuit to the quaternary circuit of capital. Financialization implies not only the financialization of existing economies (i.e., the restructuring of existing markets into producer and

consumer markets that are heavily tied to financial markets) but also the rise of financial markets for their own good; that is, the rise of financial markets not for the facilitation of other markets but for trade in money, credit, securities, and so on. Or, in the words of Cox (1992: p. 29), finance is increasingly becoming "decoupled from production to become an independent power, an autocrat over the real economy." The essence of a quaternary circuit is not that power shifts from the nonfinancial to the financial sector, but that financial and nonfinancial firms alike become increasingly involved in financial markets (Aalbers, 2008). And this is not a direct result of a lack of equity, but a direct result of financialization, which rewrites the rules of capital accumulation.

Like capital switching to the secondary circuit, capital switching to the quaternary circuit is liable to lead to overaccumulation and eventually to crisis. But capital switching to the quaternary circuit is in at least one way fundamentally different from capital switching to the secondary circuit: while the secondary circuit generally competes for financing in the capital market, the quaternary circuit represents the capital market as an investment channel in its own right. In that sense, financialization can be characterized as the capitalist economy taken to extremes: it is not a producer or consumer market, but a market designed only to make money. Although it can be argued that there exists a necessary link between production–consumption and financial speculation, this is not necessarily so: many of the recent crises have their roots in unstable income sources and overaccumulation, as both the Enron debacle and the current ongoing financial crisis demonstrate. In a finance-led regime of accumulation, risks that were once limited to a specific actor in the production–consumption chain become risks for all of the actors involved in a specific industry. In that sense, the quaternary circuit, which is in the first place a heuristic tool, is strongly attached to the other circuits of capital. Financialization as capital switching does not deny the necessary link between the different circuits, but, quite the contrary, it stresses the increased interdependence between the circuits of capital. In addition, it highlights how one of these circuits, the quaternary, comes to dominate the other circuits, to the disadvantage of those circuits (Aalbers, 2008).

To see what all of this means for cities, we rely again on the work of Manuel Castells, who identified four basic elements of a capitalist urban structure: production, consumption, exchange, and management (see also Rossi, 2010). Rather than discussing these four elements one by one, we here discuss the impact of the financial crisis on cities, first through a discussion of the link between housing markets and the financial crisis in the United States (including production, consumption, and exchange), second through a discussion of the impact of the crisis more generally speaking, and third through a discussion of the management of the crisis, focusing on both the failed institutional response to the financial crisis and the global and local grassroots responses to the financial crisis.

Subprime Lending in the United States

Real estate is, by definition, local as it is spatially fixed. Mortgage lending, however, has developed from a local to a national market and is increasingly a global market today (Gotham, 2006). An understanding of the financial crisis is ultimately a spatialized understanding of the linkages between local and global. Housing bubbles, faltering economies, and regulation together have shaped the geography of the financial crisis on the state and city levels in the United States. Subprime and predatory lending have affected low-income and minority communities more than others, and we therefore see a concentration of foreclosures not only in certain cities but also in certain neighborhoods (Aalbers, 2009).

The default and foreclosure crisis that was at the origins of the financial crisis has hit American households across the country, but people in some states and cities are more likely to be in foreclosure. The rise in default rates started some years ago in the Rustbelt where housing prices went down and unemployment up. The combination of lack of employment and falling housing prices is perilous as people who lose their job in a high-unemployment area not only have a smaller chance of finding a new job within a few months but also run a bigger chance of not being able to pay off their mortgage loan and might then be faced with negative equity. This implies that lenders will see higher foreclosures not only as a direct result of default but also because homeowners with financial problems in declining housing markets are less likely to sell their house, which would have enabled them to pay off their loan.

The rise of subprime lending started in the early 1990s with refinance loans, often in the poorer parts of Rustbelt cities. Increasing default rates led to a first subprime mortgage crisis in 1997–98, 10 years before the second subprime crisis (Ashton, 2009; Immergluck, 2009). Subprime mortgage lending has been growing fast, from about $35 billion (5% of total mortgage originations) in 1994 to $600 billion (20%) in 2006, 75% of which was securitized. The growth of subprime lending halted for a few years in the late 1990s as a response to the first subprime crisis, but picked up again after 2000 when subprime loans were no longer exclusively targeted at borrowers with low credit scores; 'exotic' mortgages were designed to be sold to middle-class borrowers, in particular in rapidly growing parts of the country. As a result, the fastest increases in defaults and foreclosures since 2007 were not in the Rustbelt but in the Sunbelt, where housing prices had been going up most and exotic mortgages with adjustable interest rates and teaser rates were more common. In some states like Nevada, subprime loans accounted for more than 30% of the loans originated in 2006. Subprime lending is often defined as lending to a borrower with poor credit, but this would be a misrepresentation of the essence of subprime lending, which is lending at higher fees and interest rates whether or not the borrower actually has bad credit (Aalbers, 2012b). Some estimates suggest that more than half of the subprime loans went to prime borrowers.

Up to 2006, the top 10 foreclosure cities almost exclusively consisted of Rustbelt cities. In 2007, when the crisis started, the list was a mix of Rustbelt and Sunbelt cities, but since 2008, the top 10 foreclosure cities are entirely Sunbelt cities, although Rustbelt city Detroit occasionally makes it back to the top 10. There are several such foreclosure lists, and they look slightly different, but generally speaking, cities in California now make up more than half of them, with cities in the South and Florida completing the list. The differences

across the United States are huge: the foreclosure rate in Richmond, Virginia, is almost 100 times as low as in Stockton, California, the foreclosure capital (Aalbers, 2009).

Housing prices can go down because of a structurally faltering economy, like in the Rustbelt, but also because they have been going up extremely fast, like in many cities in the Sunbelt. Housing prices in the Sunbelt were simply more inflated than elsewhere in the United States: the housing bubble was bigger and more likely to bust. In addition, some local and regional economies in the Sunbelt also showed signs of a declining economy, perhaps not structurally, as in the Rustbelt, but conjuncturally. Furthermore, high economic growth also meant a lot of new construction and more homeowners who recently bought a house, thereby increasing the pool of possible victims of falling housing prices. Finally, several states in the United States geared up their own regulations to impede some of the many excesses of subprime lending. As Wyly et al. (2009) have shown, states like North Carolina, New Mexico, Massachusetts, and West Virginia regulate a wide range of practices related to foreclosure rules, loan flipping, prepayment penalties, and other things. New Mexico, for example, introduced the Home Loan Protection Act in 2003.

Most subprime loans are granted to people to refinance their mortgages or as second mortgages (Squires, 2004). This means that most of these loans do not enable homeownership among low-income and minority groups, as is often argued. Subprime, and in particular predatory, loans frequently result in mortgage foreclosures at the individual level and housing abandonment at the neighborhood level. It is not just defaulting borrowers who are hit; in addition, there are severe spillover effects on housing prices, crime, and neighborhood decline. Although some cities in the Sunbelt are now hit harder than those in the Rustbelt, on a neighborhood level the Rustbelt still tops the foreclosure lists. On the list of the most foreclosed zip codes, four are now in Detroit, while Slavic Village in Cleveland has the most foreclosure filings. From the 1950s onward, redlining and suburbanization hit this neighborhood hard. Due to a combined economic and foreclosure crisis, demand for housing has fallen so dramatically that one can now buy many homes in Slavic Village that are priced under $30 000; on eBay, you could even buy one for less than $5000. Slavic Village, now referred to as foreclosure's ground zero, has also seen a rapid increase in crime.

Besides borrowers and neighborhoods, cities are also hit hard because tax income goes down due to foreclosed properties and lower real estate prices, while expenses are increasing as a result of foreclosures and property crime (Dymski, 2010; Immergluck, 2009). Local governments around the country have cut expenses on education, infrastructure, and social services. The public school system in California alone faces a loss of $4 billion in funding. Many cities in these states, but also in countless others, are facing lower incoming taxes (in particular real estate taxes) and cuts in funding of schools, social services, garbage collection, infrastructure, and so on. One complication in the United States, and possibly elsewhere, is that local governments as well as many states are not allowed to run a deficit. While the national government tries to stimulate the economy by spending more, municipalities and many states that are faced with decreasing revenues also have to cut back on expenses. This is by no means a marginal development. State revenues in New York, a state that in no way presents a worst-case scenario, have dropped 36% in 1 year.

Crises around the World

The current financial crisis originates in the housing and mortgage markets in the United States affects financial markets and economic sectors around the world (Aalbers, 2009; French et al., 2009). A few decades ago, most mortgage lenders were local or regional institutions. Today, most mortgage lenders are national lenders who tap into the global credit market. This is not so much the case because lenders are global financial institutions – most lenders are national in scope – but because they compete for the same credit in a global market. The idea was that in the wider credit market, it would be easy for mortgage lenders to get money, as mortgages were considered low risk. Mortgages would be an ideal investment for low-risk investors; cheaper credit, in return, would lower interest rates on mortgage loans. Fannie Mae and Freddie Mac, two government-sponsored enterprises that were meant to spur homeownership rates for low- and middle-income households, already introduced securitization in the 1960s. Securitization enables mortgage lenders to sell their mortgage portfolio on the secondary mortgage market to investors (Aalbers, 2012b).

The credit crisis started in 2007 when foreclosure and default rates went up and housing prices went down. This implied that investing in mortgages was not as low risk as people thought. The value of residential mortgage-backed securities (RMBS) fell even more dramatically. This is the case not only because many people had mortgage loans that were granted without down payments, but also because RMBS were sold with the idea of high returns. These high returns were partly based on high interest rates and not just on the value of the house, and partly on speculation, which increased the value of RMBS beyond what they were actually worth. In sum, not only were risks underestimated, but also returns were overestimated (even if there had not been rising defaults). In addition, even though housing prices on average fell by 20%, the impact on the RMBS market was much bigger. This is a result of not just inflationary prices but also leveraging. Major players in the RMBS market like investment banks basically invested with borrowed money (ratios of 1:20 were not uncommon, with 1:14 being the average) and because of this leveraging both profits and losses would be disproportionally big.

It now becomes easier to understand why the impact of partly local and partly national problems in housing and mortgage markets is global in scope and also affects other credit markets. The crisis hits not just investment banks on Wall Street, European banks, and pension funds that bought RMBS, but also individual investors and cities and towns around the globe. The example of Narvik in the far north of Norway is widely discussed (e.g., Aalbers, 2009). The city council of Narvik (population: 18 000) and three small, nearby municipalities had invested $78 million of the revenues of a nearby hydroelectric plant in RMBS and other products

offered by investment banks – and they lost most of it. The city's investments were meant for the construction of a new school, a nursing home, and a child-care facility. Instead, the city has cut the budget, and as a result several small rural schools will be closed, budgets for elderly care have been cut, the city is behind payments to civil servants, and the fire department will seize their 24/7 service and will switch to daytime service (in a city with mostly wooden houses). The Norwegian state has declared not to help Narvik and other municipalities, as it does not want to set a precedent by which the national state has to bear the losses of local authorities.

Of course, Narvik is not the exception. Cities and towns around the globe have been hit by the financial crisis. We could tell stories of cities in Greece, Spain, Ireland, and Iceland that have all been severely hit, but also of cities in countries that seemed to weather the financial crisis, whether they are located in Germany, Turkey, Brazil, China, or Australia. In some way, the crisis is felt in most economic sectors and in most places around the world. The only partial inclusion of, for instance, China in the global capitalist system has meant that production growth was slowed down but not that the country entered a recession. Yet, the rapid increase in the number of vacant luxury apartments in Chinese cities suggests that Chinese capitalism is also feeding local and national real estate bubbles – bubbles that result from a switching crisis and may one day result in a crisis of real estate and perhaps a larger economic crisis in China and likely elsewhere. It is crucial to link the spatial and temporal dimensions of local and global crises alike.

Cities, pension funds, sovereign wealth funds, and individuals around the world had invested in RMBS or the financial institutions that sank in this crisis such as the American Lehman Brothers or the Icelandic Landsbanki. Narvik illustrates well how connected the world has become in the twenty-first century. It also illustrates well that the world is not flat today: the old geography of local housing markets has not been replaced by a global housing market, but by a chain that starts local (a mortgage loan on a particular property), turns national (through lenders), then turns global (in the RMBS market) and then local again (by the effects in places like Narvik). Nearly everyone in North America, Europe, and Australia, and many in Asia, are in some way involved in this crisis, often as passive investors (e.g., through pension funds or investments by their local governments). We may not all be capitalists now, but most of us are investors, whether we want – or know – it or not.

Crisis Management

The financial crisis and its aftermath are often seen as a crisis of neoliberalism, and although it could be seen this way, what we have witnessed in the last couple of years is not the dismantling of neoliberalism but, by and large, the furthering of neoliberalism (IJURR, 2013). The financial crisis is leading to cutback after cutback. A core element of the state response to the crisis has, in the first place, been the government bailout of private companies, on the one hand, and austerity measures for everybody else, on the other. And although there is now a lot of talk about more regulation, a lot of this will not necessarily be unbeneficial to the neoliberal agenda. Moreover, the end result of this crisis may very well be the further dismantling of the welfare state. There are already many examples that point in this direction, at both the local and the national levels (IJURR, 2010, 2013).

The power of neoliberalism is that it furthers its agenda in economic boom periods as well as in economic bust periods. This is also visible in many European countries with relatively strong welfare states, where the current crisis provides neoliberals with the opportunity to cut money on state spending and to further the commodification of labor power, for example, by adjusting collective labor agreements or by forcing workers to choose between unemployment for some and wage cuts for all. The story is now repeating itself, not just in American cities hit hard by foreclosures such as Stockton, California, and Cleveland, Ohio, but also in many European countries, from hard-hit ones like Greece, Spain, Iceland, and Ireland to less affected ones such as the United Kingdom, France, Germany, and the Netherlands. Both local and national governments around the globe face public cuts. Ironically, neoliberalism is to blame for the problems but also prescribes the 'solution' to the problem: showering giant corporations with public money and cutting all other public spending (IJURR, 2013). As US Secretary of State Timothy Geithner said, "We saved the economy, but we kind of lost the public doing it."

It took surprisingly long before the financial crisis resulted in mass demonstrations. The streets of Dublin remained almost empty after the government had bailed out the banks at the expense of its citizens. Cutbacks in Greece and Spain have resulted in many a demonstration, but it was the Occupy Wall Street (OWS) movement that resulted in something more akin to a global (albeit far from complete) grassroots response to the financial crisis, even though OWS itself was inspired by revolts throughout the Mediterranean region (Aalbers, 2012a). OWS has not physically occupied Wall Street; it has occupied a pocket park that was formerly known as Liberty Plaza, but renamed Zuccotti Park in 2006. At times, Brookfield, the owner of Zuccotti Park, requested New York Mayor Michael Bloomberg and the New York Police Department (NYPD) to evict the demonstrators. The NYPD has not been in favor of eviction as it is easier to contain the occupiers in one easily surveillable place than have the protestors sprawl out around Lower Manhattan. For a few weeks in the late fall of 2011, the strategy of 'Brookberg' or 'Bloomfield' seemed to be to freeze out the protesters, but on the night of 14–15 November 2011, the mayor had Liberty Plaza cleared without prior announcement. That night, about 200 people were arrested. After the plaza was cleaned, the protesters were allowed back in, but they were not allowed to put up tents or sleep on the plaza. At the time of finishing this entry, a small group of protestors continues to occupy the plaza during the day.

The problem that Brookfield has with OWS is that it is hard to discuss with the protestors what should be done for them to leave Zuccotti Park. The reason for this fundamental uncertainty is only in part a result of the heterogeneous nature of the occupiers. All social movements show a degree of heterogeneity, but most still come up with a shared agenda. OWS has

not because it fights against something that is much harder to identify: the contemporary, internationalized, financialized economy. One of the many things that the current global financial and economic crisis demonstrates is that large parts of our economy are really beyond our control and often even beyond our imagination. We used to think of the financial sector as a sector that made other things possible, a sector that enabled people to buy houses, students to go to college, and entrepreneurs to start or expand their businesses. Some might have seen financial institutions as evil, but most would agree that they were necessary evils. What the financial crisis revealed is that financial institutions engage in a great deal of activities that are not useful to the economy at all. A mortgage loan may enable someone to buy a home, but many predatory subprime loans were designed to disrupt rather than to enable homeownership. A credit default swap (CDS) may basically work like insurance, but most of them are simply bets against something. If a CDS were like fire insurance, most of them would not be taken out by homeowners but by others who plan to benefit from someone else's house burning down. The financial sector and media call that innovation, but a lot of financial innovation is simply social destruction (Aalbers, 2012a).

There is a strong political dimension to all this. First, financial institutions heavily lobby states to get what they want, not just in the United States but also elsewhere. They did not simply want less regulation, but sometimes more regulation to enable them to innovate or destruct. This is not only something that happened in the decades prior to the financial crisis, but also something that continues and is undermining reregulatory efforts. Second, states, in particular although not exclusively in the United States, have failed to protect their citizens. Financial institutions have been able to prey not only on homeowners and pensioners but also on businesses and the people who depend on them for their livelihoods. States are complicit in the crisis because they have facilitated financial innovation and destruction. Years of neoliberal restructuring, albeit in different forms and intensities, have not yet been repaired by a little more consumer protection and a little more financial regulation. The fundamental question of what state–market relations should be has hardly been addressed. There is no simple answer, and the answer is of course heavily politicized (as it should be), but the 99% are right that there is a general agreement about the underregulation and underpolicing of financial institutions (Aalbers, 2012a).

Conclusion

While in the past a mortgage bubble or a housing bubble would affect the economy through homeowners, the current bursting of these bubbles affects the economy not just through homeowners but also through financial markets. Because lenders are now national in scope, this no longer affects only some housing markets, but all housing markets throughout a country. Housing markets may still be local or regional; mortgage markets are not. Since primary mortgage markets are national, the bubble in the national mortgage market affects all local and regional housing markets, although it clearly affects housing markets with a greater bubble more than those with a smaller bubble. In addition, secondary mortgage markets are global markets; this means that a crisis of mortgage securitization implies that investors around the globe, and therefore economies around the globe, are affected. The mortgage market crisis affects the US economy on both sides of the mortgage-lending chain – through homeowners and through financial markets – while it affects other economies in the world mostly through financial markets, not just because investors around the globe have invested in RMBS but also because the mortgage market has triggered a whole chain of events that have decreased liquidity, and this affects even agents in financial markets that have never been involved in RMBS.

The financial crisis is redrawing the world in many ways and at many levels. Financial globalization's impacts are, logically speaking, global, but that does not mean the impacts are the same around the globe, although there seem to be few financial institutions that remain unaffected by this crisis. The impact on nonfinancial institutions has been more spread out and has affected cities around the world in different ways and in different degrees. Housing bubbles, faltering economies, and regulation together have shaped the geography of the financial crisis at state and city levels in the United States. Subprime and predatory lending have affected low-income and minority communities more than others, and we therefore see a concentration of foreclosures not only in certain cities but also in certain neighborhoods, often those places inhabited by low-income and minority groups who have been excluded by earlier rounds of exclusion and exploitation. Yet, the meanings of globalization, not unlike the causes and consequences of this crisis, remain geographically uneven. It is important to understand that cities are an essential element in both, and that the fates of places like Stockton and Narvik are related not only to each other but also to those of Wall Street and Raffles Place (Singapore). The space of places is intrinsically linked to the flow of spaces.

Abstract

This is a review of how a new field of inquiry took shape. The article first examines the key features of this new field of inquiry, one that seeks to understand and document the multiple interactions of cities and the global economy in the current period. Next it examines the evolution of the scholarship on the subject, showing how in the early 1980s a large number of scholars began to explore these types of issues independently of each other, typically with very particular questions in mind rather than the more general subject of cities and the global economy. The rest of the article examines the critiques, several of the key hypotheses in this literature, and some of the themes that are emerging as an agenda for research and theory.

The Global City: Introducing a Concept and Its History

Each phase in the long history of the world economy raises specific questions about the particular conditions that make it possible. One of the key properties of the current phase is the ascendance of information technologies and the associated increase in the mobility and liquidity of capital. There have long been cross-border economic processes – flows of capital, labor, goods, raw materials. Over the last century, these took place largely within the interstate system, where the key articulators were national states and colonial empires. The international economic system was ensconced largely in this interstate system. This has changed rather dramatically during the 1990s as a result of privatization, deregulation, the opening up of national economies to foreign firms, and the growing participation of national economic actors in global markets.

It is in this context that we see a rescaling of what are the strategic territories that articulate the new system. With the partial unbundling or at least weakening of the national as a spatial unit due to privatization and deregulation and the associated strengthening of globalization, come conditions for the ascendance of other spatial units or scales. Among these are the subnational, notably cities and regions; cross-border regions encompassing two or more subnational entities; and supranational entities, such as global electronic markets and free-trade blocs. The dynamics and processes that get territorialized at these diverse scales can in principle be regional, national, or global.

We can locate the emergence of global cities in this context and against this range of instantiations of strategic scales and spatial units. In the case of global cities, the dynamics and processes that get territorialized are global. This article examines first some of the key theoretical and empirical elements of the global city model, followed by a brief history of the evolution of the literature on cities in the global economy. Section The Elements of a New Theoretical Framework is a more in-depth discussion of the organizing hypotheses of the global city model.

Sections The Global City Model: Organizing Hypotheses and New Forms of Centrality discuss two specific features: the question of place in a global economy and the question of city-to-city networks in domains other than the economic.

Elements in a New Conceptual Architecture

The globalization of economic activity entails a new type of organizational structure. To capture this theoretically and empirically requires, correspondingly, a new type of conceptual architecture. Constructs such as the global city and the global-city region are, in my reading, important elements in this new conceptual architecture. Arrighi's (1994) analysis is of interest here in that it posits the recurrence of certain organizational patterns in different phases of the capitalist world economy, but at gradually higher orders of complexity and expanded scope, and timed to follow or precede particular configurations of the world economy.

There are today several closely linked terms used to capture a particular intersection between global processes and cities (see Stren, 1996; Savitch, 1996 for overviews). The most common is world cities, a term attributed to Goethe and then relaunched in the work of Peter Hall (1966) and more recently respecified by John Friedmann (Friedmann and Goetz, 1982). Other related terms are 'supervilles' (Braudel, 1984), informational city (Castells, 1989). Choosing how to name a configuration has its own substantive rationality. The decision to formulate the term 'global city' (Sassen, 1984) stemmed out of a recognition of the specificity of the current period. The term world city has precisely the opposite attribute: it refers to a type of city which we have seen over the centuries (Braudel, 1984; Hall, 1966; King, 1990), and most probably also in much earlier periods in Asia than in the West. In this regard it could be said that most of today's major global cities are also world cities, but that there may well be some global cities that are not world cities in the full, rich sense of that term. This is partly an empirical question; further, as the global economy expands and incorporates additional cities into various cross-border networks, it is quite possible that the answer to that particular question will vary over time. Thus the fact that Miami has developed global city functions beginning in the late 1980s

does not make it a world city in that older sense of the term (Nijman, 1996). (See generally Abu-Lughod, 1999; Short and Kim, 1999.)

The Elements of a New Theoretical Framework

By the early 1980s a number of scholars had begun to study cities in the context of globalization (Walton, 1982; Ross and Trachte, 1983; Sassen, 1982; Rodriguez and Feagin, 1986). But it is one article in particular, 'The World City Hypothesis' by Friedmann and Goetz (1982) on which attention centered. This article took a variety of elements that were emerging in the research literature on cities, on the global economy, on immigration, and a number of other subjects, and sought to formalize these into several propositions about the role of cities in the global economy. The key elements in this framework were the emergence of several cities as basing points for global capital, a hierarchy (albeit a shifting one) of such cities, and the social and political consequences for these cities of being such basing points.

With the books by Castells (1989), King (1990), and Sassen (1991/2000), what had been a hypothesis in the early 1980s became a full-fledged theorization and empirical specification. These three books add important and distinct propositions to the general framework: Castells' proposition that globalization as constituted today has engendered a space of flows that reconfigures economic and political power; King's enlargement of the frame of reference to show that the highest levels of internationalization had taken place in the cities of colonial empires rather than in the center of the world economy; Sassen's proposition that it is not simply a matter of global coordination but one of the production of global control capacities and that an examination along these lines allows us to understand the role of global cities as production sites.

It is important to distinguish what is different about this literature from a broader, earlier literature on world cities prominently represented by the work of Peter Hall already in the 1960s, and a new literature on megacities especially focused on Latin America and Asia. These literatures do not have the fact of globalization and the centrality of cross-border networks connecting cities as crucial variables. The earlier literature on world cities is closer to the notion of capitals of empires: one city at the top of the power hierarchy.

In the current literature on global cities the determining factor is a cross-border, global network of cities that function as strategic sites for the management and specialized servicing of global economic operations. There is no such entity as a single global city, as there is with the capital of an empire; by definition, the global city is part of a network of cities. Similarly, an older literature focused on past world cities, as in the work of Braudel (1984), and earlier studies of major centers of world commerce and banking, as well as more recent work on urban hierarchies in the world system (Chase-Dunn, 1984), are to be differentiated from the current literature if we historicize the world economy and specify what is distinct today. Finally, we need to distinguish between a narrowly specified literature on global and world cities today and various literatures that directly or indirectly contribute to our understanding of these cities, notably the research on producer services.

By the mid-1990s the subject had clearly emerged as a rather large field for research among scholars in many different disciplines and countries. We can see this in the variety of authors and themes in several state-of-the-art collections, notably by Fainstein et al. (1993), Knox and Taylor (1995), Noller et al. (1994), Lo and Yeung (1996), and several others that elaborate, critique, expand the empirical base, and generally advance this theoretical and methodological project. We can also see it in several new important books that set the stage for highly focused research on particular variables, notably Meyer (1991), Thrift and Leyshon (1994), Keil (1993), Eade (1996) among others. We also see the creation of several book series by various publishers in different countries: the series on World Cities edited by Knox for Belhaven Press, the series edited by Milton Santos and his colleagues in Sao Paulo for Hucitec, the series edited by Martin Wentz for Campus Verlag, are just some.

It is not only the growth of the research literature but also the growth of a body of critical responses and analyses that signals the strength and vigor of this field of inquiry. There is only space here for the briefest mention, a sort of guide to criticisms: Logan and Swanstrom's (1990) critique of the excessive weight given to global structural processes in comparing internal vs. external factors that shape a city's economic development; Hamnett's (1996) critique of Sassen's proposition that globalization has contributed to social and economic polarization in global cities; Markusen and Gwiasda's (1994) critique of the notion that New York is at the top of the US urban hierarchy and how a comparison with Washington shows that the latter has a higher level of specialization than New York in many advanced specialized services, notably in legal services; critiques of the literature for its neglect of grassroots transnationalism and the new kinds of politics and identity formation that this entails; Beauregard's (1991) critique of the explanatory variables for changes in the built environment and the real estate industry; Simon's (1995) critique of the neglect of the periphery, notably Africa; the debate in *Urban Affairs* (March 1998) on the concept of the global city and a similar one in *Urban Studies* (Summer 2001); the special issue on 'Segregations Urbaines' of *Societes Contemporaines* in 1995; the special issue of *Urban Studies* in 1996, and many others.

There are two types of scholarly literature that intersect with this body of research on cities and the global economy, and indeed often invoke or use it to develop their arguments. They are on the one hand a literature of anthropological and cultural studies on transnationality, globalization, and identity formation (Holston, 1996; Low, 1999). The other is the scholarship by regional economic geographers on the global economy, who have also focused on cities (e.g., Moulaert and Scott, 1997; Gravesteijn et al., 1998). In the last few years there has been a new interest in this subject by geographers (Veltz, 1996; Scott, 2001; Storper, 1997).

In terms of method, a number of strategies have been developed. Even where there are data on intercity flows, it will take a lot of work to constitute the requisite data sets. In this regard, an ambitious initiative by the National Academy of

Sciences of the US examines how we can construct better data sets at the scale of the city (NAS, 2000).

Among the quantitative methodological and data formation strategies are the efforts by Smith and Timberlake (2002) and by Taylor et al. (2002). Smith and Timberlake (2002) conceptualize urban areas as central nodes in multiplex networks of economic, social, demographic and information flows. They use the methodological logic of network analysis, using particularly two measures: one of these is structural or relational equivalence between actors (i.e., cities) in a network; the second measure is centrality. Both of these measures relate to a number of propositions developed in the literature on cities in the global economy.

Taylor et al. (2002) have developed a new and pioneering data set that makes it possible to map the global networks of offices of the leading firms worldwide in several specialized corporate services, such as accounting, law, advertising, and finance. These networks of offices can be used to classify cities in terms of their participation in cross-border networks. The data can be analyzed using a variety of hypotheses and statistical as well as other methods.

There are several other efforts, but space dictates singling out just a few. David Meyer (1991) has developed ways of analyzing international networks through which a variety of exchanges of capital take place. Castells (1989) and Sassen (1991/2000) have developed several techniques of analysis which range from methods to understand the place of cities in global markets to expanding the representation of the global. In *The Informational City* and *The Global City* the authors sought to establish rather broadly what is the array of data sets that can be brought into an analysis of this subject – from international flows of capital and information to very localized social effects. This was an effort to resist the simplification in mainstream accounts which emphasize the global dispersal of activities and telecommunications and exclude most social issues.

Techniques for data analysis traditionally used by economic geographers can also be helpful. For instance Wheeler's (1986) examination of the dispersion of higher-order financial services throughout the US urban hierarchy – which he found had proceeded at a much slower rate than the dispersion of headquarters of other large corporations – can also be used for cross-border hierarchies. Wheeler found that corporations tend to proceed up the urban hierarchy for their advanced service and banking needs.

Elliott (1999) developed a test for the socioeconomic polarization hypothesis in global cities.

The Global City Model: Organizing Hypotheses

There are seven core hypotheses that organize the data and the theorization of the global city model. There follows a brief discussion of each as a way of producing a more precise representation of the model. (See Sassen, 1991/2000.)

First, the geographic dispersal of economic activities that marks globalization, along with the simultaneous integration of such geographically dispersed activities, is a key factor feeding the growth and importance of central corporate functions. The more dispersed a firm's operations across different countries, the more complex and strategic its central functions – that is, the work of managing, coordinating, servicing, financing a firm's network of operations.

Second, these central functions become so complex that increasingly the headquarters of large global firms outsource them: they buy a share of their central functions from highly specialized service firms: accounting, legal, public relations, programming, telecommunications, and other such services. Thus while even 10 years ago the key site for the production of these central headquarter functions was the headquarters of a firm, today there is a second key site: the specialized service firms contracted by headquarters to produce some of these central functions or components of them. This is especially the case with firms involved in global markets and non-routine operations. But increasingly the headquarters of all large firms are buying more of such inputs rather than producing them in-house.

Third, those specialized service firms engaged in the most complex and globalized markets are subject to agglomeration economies. The complexity of the services they need to produce, the uncertainty of the markets they are involved with either directly or through the headquarters for which they are producing the services, and the growing importance of speed in all these transactions, is a mix of conditions that constitutes a new agglomeration dynamic. The mix of firms, talents, expertise from a broad range of specialized fields makes a certain type of urban environment function as an information center. Being in a city becomes synonymous with being in an extremely intense and dense information loop. This is a type of information loop that as of now still cannot be replicated fully in electronic space, and has as one of its value-added features the fact of unforeseen and unplanned mixes of information, expertise, and talent; these can produce a higher order of information. This does not hold for routinized activities which are not as subject to uncertainty and non-standardized forms of complexity. Global cities are, in this regard, production sites for the leading information industries of our time.

A fourth hypothesis, derived from the preceding one, is that the more headquarters outsource their most complex, unstandardized functions particularly those subject to uncertain and changing markets and to speed, the freer they are to opt for any location because the more the work actually done in the headquarters is not subject to agglomeration economies. This further underlines that the key sector specifying the distinctive production advantages of global cities is the highly specialized and networked services sector. In developing this hypothesis I was responding to a very common notion that the number of headquarters is what specifies a global city. Empirically it may still be the case in many countries that the leading business center is also the leading concentration of headquarters, but this may well be because there is an absence of alternative locational options. But in countries with a well developed infrastructure outside the leading business center, there are likely to be multiple locational options for such headquarters.

Fifth, these specialized service firms need to provide a global service which has meant a global network of affiliates or some other form of partnership, and as a result we have seen a strengthening of cross-border city-to-city transactions and networks. At the limit this may well be the beginning of the formation of transnational urban systems. The growth of global

markets for finance and specialized services, the need for transnational servicing networks due to sharp increases in international investment, the reduced role of the government in the regulation of international economic activity, and the corresponding ascendance of other institutional arenas, notably global markets and corporate headquarters – all these point to the existence of a series of transnational networks of cities. One implication of this, and a related hypothesis for research is that the economic fortunes of these cities become increasingly disconnected from their broader hinterlands or even their national economies. We can see here the formation, at least incipient, of transnational urban systems. To a large extent it seems to me that the major business centers in the world today draw their importance from these transnational networks.

A sixth hypothesis, is that the growing numbers of high level professionals and high-profit making specialized service firms have the effect of raising the degree of spatial and socioeconomic inequality evident in these cities. The strategic role of these specialized services as inputs raises the value of top level professionals and their numbers. Further, the fact that talent can matter enormously for the quality of these strategic outputs and, given the importance of speed, proven talent is an added value, the structure of rewards is likely to experience rapid increases. Types of activities and of workers lacking these attributes, notably in manufacturing and industrial services, are likely to get caught in the opposite cycle.

A seventh hypothesis, is that one result of the dynamics described in hypothesis six, is the growing informalization of a range of economic activities which find their effective demand in these cities yet have profit rates that do not allow them to compete for various resources with the high-profit making firms at the top of the system. Informalizing part or all production and distribution activities, including of services, is one way of surviving under these conditions.

The first four hypotheses qualify what has emerged as a dominant discourse on globalization, technology, and cities, which posits the end of cities as important economic units or scales. There is a tendency in that account to take the existence of a global economic system as a given, a function of the power of transnational corporations and global communications. According to the global city model, the capabilities for global operation, coordination, and control contained in the new information technologies and in the power of transnational corporations need to be produced. By focusing on the production of these capabilities we add a neglected dimension to the familiar issue of the power of large corporations and the capacity of the new technologies to neutralize distance and place. A focus on the production of these capabilities shifts the emphasis to the practices that constitute what we call economic globalization and global control.

A focus on practices draws the categories of place and work process into the analysis of economic globalization. These are two categories easily overlooked in accounts centered on the hypermobility of capital and the power of transnationals. Developing categories such as place and work process does not negate the centrality of hypermobility and power. Rather, it brings to the fore the fact that many of the resources necessary for global economic activities are not hypermobile and are, indeed, deeply embedded in place, notably places such as global cities, global-city regions, and export processing zones.

This entails a whole infrastructure of activities, firms, and jobs necessary to run the advanced corporate economy. These industries are typically conceptualized in terms of the hypermobility of their outputs and the high levels of expertise of their professionals rather than in terms of the production or work process involved and the requisite infrastructure of facilities and non-expert jobs that are also part of these industries. This in turn brings with it an emphasis on economic and spatial polarization because of the disproportionate concentration of very high and very low income jobs in the city compared with what would be the case at a larger scale such as the region or the country. A focus on regions, in contrast will lead to an emphasis on broad urbanization patterns, a more encompassing economic base, more middle sectors of both households and firms. Emphasizing place, infrastructure, and non-expert jobs matters precisely because so much of the focus has been on the neutralization of geography and place made possible by the new technologies.

Dealing with place brings with it the problem of boundaries. These are at least of two sorts, the boundary of the territorial scale as such and the boundary of the spread of globalization in the organizational structure of industries, institutional orders, places, and so on. In the case of the global city it is possible to opt for an analytic strategy that emphasizes core dynamics rather than the unit of the city as a container – the latter being one that requires territorial boundary specification. Emphasizing core dynamics and their spatialization (in both actual and digital space) does not completely solve the boundary problem, but it does allow for a fairly clear trade-off between emphasizing the core or center of these dynamics and their spread institutionally and spatially.

Finally, the detailed examination of three particular cities (Sassen, 1991/2000) brought to the fore the extent to which these cities collaborate through their very specific advantages rather than simply competing with each other. In focusing on global finance in the 1980s and 1990s it becomes clear that the growth of the major centers was partly derived from the growing network of financial centers. In looking at the broader network it also becomes clear to what extent it was and remains characterized by a pronounced hierarchy among the growing number of centers that make up the network.

The growth of networked cross-border dynamics among global cities includes a broad range of domains – political, cultural, social, criminal. There are cross-border transactions among immigrant communities and communities of origin and a greater intensity in the use of these networks once they become established, including for economic activities that had been unlikely until now. We also see greater cross-border networks for cultural purposes, as in the growth of international markets for art and a transnational class of art curators; and for non-formal political purposes, as in the growth of transnational networks of activists around environmental causes, human rights, and so on. These are largely city-to-city cross-border networks, or, at least, it appears at this time to be simpler to capture the existence and modalities of these networks at the city level. The same can be said for the new cross-border criminal networks.

In brief, recapturing the geography of places represented by the network of global cities allows us to recapture people, workers, communities, and more specifically, the many different work cultures, besides the corporate culture, involved in the work of globalization. It also brings with it an enormous research agenda, one that goes beyond the by now familiar focus on cross-border flows of goods, capital and information.

Further, by emphasizing the fact that global processes are at least partly embedded in national territories, such a focus introduces new variables in current conceptions about economic globalization and the shrinking regulatory role of the state. That is to say, the space economy for major new transnational economic processes diverges in significant ways from the duality global/national presupposed in much analysis of the global economy. The duality national vs global suggests two mutually exclusive spaces – where one begins the other ends. One of the outcomes of a global city analysis is that it makes evident that the global materializes by necessity in specific places and institutional arrangements a good number of which, if not most, are located in national territories.

The two final sections examine two particular aspects that illustrate some of these issues concerning place in a global economy and city-to-city networks in realms other than the economic.

New Forms of Centrality

Several of the organizing hypotheses in the global city model concern the conditions for the continuity of centrality in advanced economic systems in the face of major new organizational forms and technologies that maximize the possibility for geographic dispersal. Historically, centrality has largely been embedded in the central city. Have the new technologies and organizational forms altered the spatial correlates of centrality?

Today there is no longer a simple straightforward relation between centrality and such geographic entities as the downtown, or the central business district (CBD). In the past, and up to quite recently in fact, the center was synonymous with the downtown or the CBD. The spatial correlate of the center can assume several geographic forms. It can be the CBD, as it still is largely in New York City, or it can extend into a metropolitan area in the form of a grid of nodes of intense business activity, as we see for instance in Frankfurt and Zurich. The center has been profoundly altered by telecommunications and the growth of a global economy, both inextricably linked; they have contributed to a new geography of centrality (and marginality). Simplifying we can identify four forms assumed by centrality today.

First, while centrality can assume multiple spatial correlates, the CBD in major international business centers remains a strategic site for the leading industries. But it is one profoundly reconfigured by technological and economic change (Graham and Marvin, 1996). Further, there are often sharp differences in the patterns assumed by this reconfiguring of the central city in different parts of the world, notably the United States and Western Europe (Veltz, 1996; Kunzmann, 1994).

In the United States, major cities such as New York and Chicago have large centers that have been rebuilt many times, given the brutal neglect suffered by much urban infrastructure and the imposed obsolescence so characteristic of US cities. This neglect and accelerated obsolescence produce vast spaces for rebuilding the center according to the requirements of whatever regime of urban accumulation or pattern of spatial organization of the urban economy prevails at a given time. In Europe, urban centers are far more protected and they rarely contain significant stretches of abandoned space; the expansion of workplaces and the need for intelligent buildings necessarily will have to take place partly outside the old centers. One of the most extreme cases is the complex of La Defense, the massive, state-of-the-art office complex developed right outside Paris to avoid harming the built environment inside the city. This is an explicit instance of government policy and planning aimed at addressing the growing demand for central office space of prime quality. Yet another variant of this expansion of the 'center' onto hitherto peripheral land can be seen in London's Docklands. Similar projects for recentralizing peripheral areas were launched in several major cities in Europe, North America, and Japan during the 1980s. (See Marcuse and van Kempen, 2000.)

Second, the center can extend into a metropolitan area in the form of a grid of nodes of intense business activity. One might ask whether a spatial organization characterized by dense strategic nodes spread over a broader region does in fact constitute a new form of organizing the territory of the 'center', rather than, as in the more conventional view, an instance of suburbanization or geographic dispersal. Insofar as these various nodes are articulated through digital networks, they represent a new geographic correlate of the most advanced type of 'center'. This is a partly deterritorialized space of centrality. Indeed much of the actual geographic territory within which these nodes exist falls outside the new grid of digital networks, and is in that sense partly peripheralized.

This regional grid of nodes represents a reconstitution of the concept of region. Far from neutralizing geography the regional grid is likely to be embedded in conventional forms of communication infrastructure, notably rapid rail and highways connecting to airports. Ironically perhaps, conventional infrastructure is likely to maximize the economic benefits derived from telematics. This is an important issue that has been lost somewhat in discussions about the neutralization of geography through telecommunications.

Third, we are seeing the formation of a transterritorial 'center' constituted, partly in digital space, via intense economic transactions in the network of global cities. These networks of major international business centers constitute new geographies of centrality. The most powerful of these new geographies of centrality at the global level binds the major international financial and business centers: New York, London, Tokyo, Paris, Frankfurt, Zurich, Amsterdam, Los Angeles, Sydney, Hong Kong, among others. But this geography now also includes cities such as Bangkok, Seoul, Taipei, Sao Paulo, Mexico City. The intensity of transactions among these cities, particularly through the financial markets, trade in services, and investment, has increased sharply, and so have the orders of magnitude involved. At the same time, there has been a sharpening inequality in the concentration of strategic

resources and activities between each of these cities and others in the same country, a condition that further underlines the extent to which this is a cross-border space of centrality.

The pronounced orientation to the world markets evident in such cities raises questions about the articulation with their nation-states, their regions, and the larger economic and social structure in such cities. Cities have typically been deeply embedded in the economies of their region, indeed often reflecting the characteristics of the latter; and they still do. But cities that are strategic sites in the global economy tend, in part, to disconnect from their region. This conflicts with a key proposition in traditional scholarship about urban systems, namely, that these systems promote the territorial integration of regional and national economies.

In the case of a complex landscape such as Europe's we see several geographies of centrality, one global, others continental and regional. A central urban hierarchy connects major cities, many of which in turn play central roles in the wider global system of cities: Paris, London, Frankfurt, Amsterdam, Zurich. These cities are also part of a wider network of European financial/cultural/service capitals, some with only one, others with several of these functions, which articulate the European region and are somewhat less oriented to the global economy than Paris, Frankfurt, or London. And then there are several geographies of marginality: the East–West divide and the North–South divide across Europe as well as newer divisions. In Eastern Europe, certain cities and regions, notably Budapest, are rather attractive for purposes of investment, both European and non-European, while others will increasingly fall behind, notably in Rumania, Yugoslavia, and Albania. We see a similar differentiation in the south of Europe: Madrid, Barcelona, and Milan are gaining in the new European hierarchy; Naples, Rome, and Marseilles are not quite.

Fourth, new forms of centrality are being constituted in electronically generated spaces. For instance, strategic components of the financial industry operate in such spaces. The relation between digital and actual space is complex and varies among different types of economic sectors. But it is increasingly becoming evident that the highly complex configurations for economic activity located in digital space contain points of coordination and centralization.

The Global City as a Nexus for New Politico-cultural Alignments

The incorporation of cities into a new cross-border geography of centrality also signals the emergence of a parallel political geography. Major cities have emerged as strategic sites not only for global capital, but also for the transnationalization of labor and the formation of translocal communities and identities (Smith, 1997). In this regard cities are sites for new types of political operations and for a whole range of new 'cultural' and subjective operations (Watson and Bridges, 1999; Allen et al., 1999). The centrality of place in a context of global processes makes possible a transnational economic and political opening for the formation of new claims and hence for the constitution of entitlements, notably rights to place. At the limit, this could be an opening for new forms of 'citizenship' (Isin, 2000; Holston, 1996).

The emphasis on the transnational and hypermobile character of capital has contributed to a sense of powerlessness among local actors, a sense of the futility of resistance. But an analysis that emphasizes place suggests that the new global grid of strategic sites is a terrain for politics and engagement. The loss of power at the national level produces the possibility for new forms of power and politics at the subnational level. Further, insofar as the national as container of social process and power is cracked (Brenner, 1998; Taylor, 1995) it opens up possibilities for a geography of politics that links subnational spaces across borders. Cities are foremost in this new geography. One question this engenders is how and whether we are seeing the formation of a new type of transnational politics that localizes in these cities.

Immigration, for instance, is one major process through which a new transnational political economy and translocal household strategies are being constituted (Portes, 1995; Skeldon, 1997). It is one largely embedded in major cities insofar as most immigrants, certainly in the developed world, whether in the US, Japan, or Western Europe, are concentrated in major cities. It is, in many regards, one of the constitutive processes of globalization today, even though not recognized or represented as such in mainstream accounts of the global economy. This configuration contains unifying capacities across national boundaries and sharpening conflicts within cities. Global capital and the new immigrant workforce are two major instances of transnationalized actors that have unifying properties across borders, and thus internally to each, and find themselves in contestation with each other inside cities. Researching and theorizing these issues will require approaches that diverge from the more traditional studies of political elites, local party politics, neighborhood associations, immigrant communities, and so on through which the political landscape of cities and metropolitan regions has been conceptualized in urban studies.

One way of thinking about the political implications of this strategic transnational space anchored in global cities is in terms of the formation of new claims on that space. The city has indeed emerged as a site for new claims: by global capital which uses the city as an 'organizational commodity', but also by disadvantaged sectors of the urban population, frequently as internationalized a presence in large cities as capital. The 'denationalizing' of urban space and the formation of new claims by transnational actors, raise the question 'Whose city is it?'

This is a space that is both place-centered in that it is embedded in particular and strategic locations; and it is transterritorial because it connects sites that are not geographically proximate yet are intensely connected to each other. If we consider that large cities concentrate both the leading sectors of global capital and a growing share of disadvantaged populations – immigrants, many of the disadvantaged women, people of color generally, and, in the megacities of developing countries, masses of shanty dwellers – then we can see that cities have become a strategic terrain for a whole series of conflicts and contradictions (Allen et al., 1999; Tardanico and Lungo, 1995). We can then think of cities also as one of the sites for the contradictions of the globalization of capital, even though the city cannot be reduced to this dynamic.

Conclusion

An examination of globalization through the concept of the global city introduces a strong emphasis on strategic components of the global economy rather than the broader and more diffuse homogenizing dynamics we associate with the globalization of consumer markets. As a consequence, this also brings an emphasis on questions of power and inequality. And it brings an emphasis on the actual work of managing, servicing, and financing a global economy. Second, a focus on the city in studying globalization will tend to bring to the fore the growing inequalities between highly provisioned and profoundly disadvantaged sectors and spaces of the city, and hence such a focus introduces yet another formulation of questions of power and inequality.

Third, the concept of the global city brings a strong emphasis on the networked economy because of the nature of the industries that tend to be located there: finance and specialized services, the new multimedia sectors, and telecommunications services. These industries are characterized by cross-border networks and specialized divisions of functions among cities rather than international competition per se. In the case of global finance and the leading specialized services catering to global firms and markets – law, accounting, credit rating, telecommunications – it is clear that we are dealing with a cross-border system, one that is embedded in a series of cities, each possibly part of a different country. It is a *de facto* global system.

Fifth, a focus on networked cross-border dynamics among global cities also allows us to capture more readily the growing intensity of such transactions in other domains – political, cultural, social, criminal.

Global cities around the world are the terrain where a multiplicity of globalization processes assume concrete, localized forms. These localized forms are, in good part, what globalization is about. Recovering place means recovering the multiplicity of presences in this landscape. The large city of today has emerged as a strategic site for a whole range of new types of operations – political, economic, 'cultural', subjective. It is one of the nexus where the formation of new claims, by both the powerful and the disadvantaged, materializes and assumes concrete forms.

Cities: Internal Structure

Elisabeth Lichtenberger, University of Vienna, Vienna, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article concentrates on big cities in western societies and the changing principles of urban development since the twentieth century. It combines general principles and the dual cycle theory of urban expansion and urban renewal with the impact of political systems and cultural environments.

Three general principles are formative for the internal structure of cities:

1. The accessibility determined by transport technology.
2. The so-called 'distance-decay' from center to periphery, defined by the social gradient and the land values gradient.
3. The hierarchical organization of urban space.

The dual cycle theory of urban development, explains urban decay as a consequence of the time lag between urban expansion and urban renewal. Development differs greatly depending on whether it takes place under private capitalism, in welfare states, or in postsocialist countries.

Three periods of urban development are distinguished. After World War II the system of centered cities dating from the period of Europeanization of the globe, was superseded by city models derived from North America.

During the period AD 1950–2000, a rapidly growing system of suburbia created a sort of extensive – though not ubiquitous – network. The combination of 'urban-like,' suburban structures and new megastructures seems to correspond to postindustrial America's abandonment of the areas of earlier industrial-city development.

In the foreseeable future, however, twenty-first century city development is unlikely to follow North American models much longer. All over the globe – in the geo-strategically and economically newly relevant BRIC (Brazil, Russia, India, and China) countries as well as in all countries of the Islamic world – decision makers have recognized that the inherent functioning of cities (above all of metropolises and capital cities) with the help of state-of-the-art technologies, has gained in importance. Megacities in these regions with populations of 20 million and more surpass all European and North American big cities.

General Principles

Accessibility and Transport Technology

The city is a centered system based on the twofold premise that the city center is the engine of development and the place easiest to access. Accessibility of both the center and the entire city area is determined by its opening up for development and by transport technology (see **Figure 1**).

A city of pedestrians and coaches tended to be circular. When streetcars came into use in Europe, they started mostly at the town gates. This made for star-shaped growth, with the interstitial areas lagging behind in development. Where public transport is predominant, the city center remains the place of highest access to the metro region. The *métropole concentrée* of Paris is an example.

The Regie Autonome de Transports Parisiens transports more than 3 billion passengers (2011) annually, half of them underground (http://wikipedia rg/wiki/RATP; 12 December 2013).

The absolute predominance of private transport reduces access to the center; under a liberal political system and with land abundantly available, a city or metropolitan region designed for car traffic emerges. Los Angeles offers a prototype of this; the City of Los Angeles Transportation Authority (Los Angeles Department of Transportation (LADOT)), for example, moves only about 30 million passengers per year (http://www.discoverlosangeles.com/blog/los-angeles-public-transit; 12 December 2013) although the population of LA is significantly larger than that of Paris.

Distance Decay

There are two theoretical approaches for analyzing gradients from the center to the periphery.

Social Gradients

The central-peripheral organization of urban society may be described by means of centrifugal and centripetal social gradients. These gradients permit the following diagnosis regarding urban growth. Wherever the city center is also the social center and a centripetal social gradient is in evidence, the demand for space of the upper classes extends outward from the center. This causes residential and social upgrading of the adjacent middle class districts. In the middle zone, former lower class quarters are turned into middle class districts. The Founders Period growth of Berlin, Budapest, Copenhagen, Paris, Prague, and Vienna was of this kind. This type of upgrading must not be confused with the recent phenomenon of gentrification in North American cities. Here, middle and upper income urbanites move centripetally into rundown central districts (see **Figure 2**).

Wherever a centrifugal social gradient predominates, as in US cities, a filtering down takes place, with the deterioration of the building fabric in the center; lower class people move outward into adjacent middle and upper class districts. This social downgrading of high-quality living quarters is hard to stop and presented a major problem for British town planners. Having accomplished the redevelopment of rundown early industrial terrace houses next to the old town centers, they were faced with the daunting task of redeveloping devastated mid- and late-nineteenth centuries terrace house districts (the necessary renovation of early twentieth century council housing was partly effected by privatization under Thatcher).

Land Values Gradient

According to the theory of urban land markets (Alonso, 1964), transport costs determine land rents and therefore

Figure 1 The accessibility of the city center. Lichtenberger, E., 1998. Stadtgeographie (Urban Geography), third ed. Teubner, Stuttgart, Leipzig, Germany. Italian translation: Geografia dello spazio urbano, first ed. Unicopli, Milano, ill. 2.30, p. 103.

urban land uses. Regularly, in socioeconomically intact city centers, there is a center-periphery gradient with several consecutive zones of use, outward from the central business district (CBD). Replacement of historical city-models by the new model of suburbia has made for abandonment of central areas, resulting in 'craters' of land prices and visible decay of inner cities in the United States. As there are no efficient means of public transport, inhabitants of the centers of most metropolitan areas are at a disadvantage. Detroit is the classic example of a dying US-American metropolitan area.

The Alonso model excludes restrictions on planning land use and vertical development. With zoning laws, building categories, and other legal regulations, the gradient of real estate prices is altered. Each category or zone is divided in two, with the inner zone obviously better suited for business purposes and office space than the outer zone that is used for dwelling as it is more profitable (see Figure 3).

Hierarchical Structures

Hierarchical order is one of the basic types of systemic organization. When organizing the physical space of urban areas, a hierarchical order has been attempted wherever planned development was feasible and land in abundant supply. Examples run from seventeenth century Sicily (Granmichele) via Howard's New Town idea (1902) (with city center and garden suburbs in a cluster city), to major planning projects for urban peripheries in Europe at present. The hierarchy is constructed from the bottom upward. The basic units are electoral ward, whose dimensions in many European countries and in North America are derived from the traditional 'pedestrian ideology' of 1 km (i.e., 15 min walking distance) as the determinant of standard size. Comprehensive hierarchical urban structures have been realized only in the former Socialist countries of Eastern Europe, above all the USSR. In the rest of Europe, hierarchical organization of urban space is the exception rather than the rule.

The Impact of Political Systems

Social-Ecological City Models

In their paper, *The Nature of Cities* (1945), Harris and Ullman tried to model internal patterns within cities. The triad of models presented makes use of diverse development phenomena:

1. invasion and succession of social groups in Burgess' zonal model,
2. transport-induced ribbon-developments along traffic lines in Hoyt's sector model, and
3. collective preferences in respect of the allocation of workplaces in the Harris–Ullman multiple-nuclei model.

However, three important underlying assumptions have not yet been made explicit:

1. the political system of liberalism,
2. the historical 'one-dimensionality' of urban development, and
3. the concept of the city center as CBD.

The models mentioned represent ideal types of North American cities of the interwar period (see Figure 4).

Historical-Political Systems and the Concept of the City Center

Changes in the political system alter the conceptions of the city and urban society. The function of the city center is changed. European urban development may be defined as a succession of four types of political systems and corresponding types of cities (Lichtenberger, 1970, 1976).

The concepts of the city center were markedly different in each of the four cases:

1. In the burghers' city of the medieval feudal territorial state, the marketplace was the social center.
2. The center shifted to the ruler's residence in the residence city of the absolutist state. Thus, a social gradient falling from the center toward the periphery is the general rule in preindustrial cities.
3. In the age of liberalism, Great Britain created the prototype of the industrial city. A social gradient rising from the center toward the periphery predominated, a development later paralleled in North American cities.

Figure 2 Centrifugal and centripetal social gradients. Lichtenberger, E., 1998. Stadtgeographie (Urban Geography), third ed. Teubner, Stuttgart, Leipzig, Germany. Italian translation: Geografia dello spazio urbano, first ed. Unicopli, Milano, ill. 2.35, p. 110.

4. Again, Great Britain set the rules for the New Town idea; the attempt at structuring the amorphous masses of big industrialized cities on a human scale, with the city divided into parts with different functions. From the outset, spatial segregation of inhabitants was barred from the design of New Towns – a fact that is still influential in urban planning today. European city development is most complex; various superpositions and (to different degrees) the persistence of historical structures, caused the diversification of socioeconomic patterns and the creation of different social gradients.

Vienna in the 1960s offers the model for the traditional continental European city (Lichtenberger, 1993b):

1. Social status is still highest in the core and declines toward the periphery. Depending on site preferences, individual districts deviate from this rule.
2. The CBD has maintained some residential functions and is not surrounded by slums, but by middle and upper class residential districts, encircled by lower class quarters.
3. The wide belt of multistory blocks is followed on its outside by Founders Period industrial quarters, followed in their turn by loosely built-up districts.
4. The fringe zone is not defined by an extensive speculation area of 'vacant land' as in North America, but by sectors of intensive agricultural land use (in keeping with the von Thünen model) such as truck farming and viticulture, as well as allotment gardens and weekend homes (see **Figure 5**).

The Impact of State Socialism

Under state socialism, municipal governments were the local planning authorities, responsible for the mass of multistory housing that was unprofitable because of 'social' low rents. They lost all chances of capital accumulation from real estate property and became dependent on financial endowments from the central government and on central planning. The consequences were:

Big cities' increasing demand for space was met by extensive incorporations.
Public construction (by state, municipal, and other collective institutions) took absolute precedence over private construction.
Architectural design followed totalitarian principles, stressing elements of over-wide avenues and huge squares, both imposing and strategically important.
Massive antisegregation strategies were pursued.
Entire old city centers were listed on historical registers.
City enlargement was effected via New Cities in the shape of hierarchically structured giant multistory blocks.
In compliance with the Charter of Athens, industrial and dwelling zones were strictly separated.
Commuting requirements were taken care of by subway construction.
Forced industrialization created extensive industrial zones with plants located close to railway lines and superhighways.

Figure 3 Land values gradient and zoning. Lichtenberger, E., 1998. Stadtgeographie (Urban Geography), third ed. Teubner, Stuttgart, Leipzig, Germany. Italian translation: Geografia dello spazio urbano, first ed. Unicopli, Milano, ill. 2.3, p. 107.

Extensive leisure zones were created on the fringes, with both collective recreation facilities and private second homes (see Figure 6).

City Growth and Political Systems

Cities are growing systems, with increasing populations and/or with increasing demand for space for diverse urban functions (housing, work, education, leisure, traffic, etc.) in a setting of economic growth and technical innovation.

The diverging political-economic effects of central planning and of a free enterprise economy cause significant differences in the physical growth of cities in particular systems. Cities grow in two directions: laterally and vertically (Lichtenberger, 1992).

The Third Dimension

Vertical growth means high-rise construction. Up to the 1970s, when some cities changed their laws, European cities could not expand vertically because of strict zoning laws, but were forced to grow laterally. This necessitated the conversion of dwelling space into office space, e.g., in Paris and Vienna. High-rise construction in European cities started relatively late (see Figure 7). Its location within the city – frequently subject to special permission – is different from that in North America. There, the vertical structure of urban skylines shows that land prices peak in the center while in European cities 'monument protection' bars high-rises from the centers. Thus, the new landmarks of banks, insurance firms, corporation headquarters, and hotels keep a polite distance from the old landmarks of churches, town halls, and palaces.

For the sake of access to the various supply and disposal mains, high-rises are preferably located along urban 'scars': at the interfaces of traditional zones where former boundaries still show in open space or low physical objects. Frequently, new high-rises accent not only the edge of traditional inner cities but also, major points of access to older outer cities and suburbs. High-rises also mark the front of growth of the CBD, busy commuter train stations, as well as 'satellite' districts. They are also instrumental in slum clearing.

Development of Urban Fringes

The development of urban fringes differs materially depending on whether it takes place under private capitalism, in welfare states or, in retrospect, under state capitalism.

1. Under US private capitalism, cities grow as profits from land speculation and rising land prices are invested in land development and in technical improvements. This starts an upward spiral of development and rising prices. North American cities show two wide zones of speculation. The inner one, around the CBD, is marked by decay and slum areas at present. Far more impressive, at least because of its

Figure 4 Social ecological models of US cities during the inter-war-period. Lichtenberger, E., 1998. Stadtgeographie (Urban Geography), third ed. Teubner, Stuttgart, Leipzig, Germany. Italian translation: Geografia dello spazio urbano, first ed. Unicopli, Milano, ill. 2.7, p. 58; Hoyt, 1939. The Structure and Growth of Residential Neighborhoods in American Cities. Federal Housing Administration, Washington, DC; and Harris C.D., Ullman, E.L.,1945. The nature of cities. The Annals of American Academy of Political and Social Sciences 242, 7–17.

Figure 5 The dual model of Vienna. Lichtenberger, E., 1998. Stadtgeographie (Urban Geography), third ed. Teubner, Stuttgart, Leipzig, Germany. Italian translation: Geografia dello spazio urbano, first ed. Unicopli, Milano, ill. 2.17, p. 78.

extent, is the peripheral zone of vacant land around core cities and suburbs, which, even in the 1950s amounted to 20–60% of core areas (Bartholomew, 1955). Anglo-American urban geography textbooks completely ignore those huge tracts of vacant land – implying that non-utilization of these spaces is taken for granted rather than considered a problem.

2. In continental Europe, too, urban fringes attracted speculation. During World War I, they were occupied by so-called 'emergency gardening plots,' and later turned into allotment gardens. Frequently, these became temporary settlements, partly forerunners of a second-home periphery. All over post-World War I continental Europe, spontaneous settlements typically marked city fringes – a consequence of fundamental political changes. The absence of government checks on land use made for temporary settlements, among them the pavilions of 'chaotic urbanization' in France as well as the often illegal occupation of land around big central European cities (Belgrade, Budapest, Bucharest, Sofia, Vienna, and Warsaw). The succession states were less successful than the Austro–Hungarian monarchy in repelling indigent illegal immigrants. Those postwar squatters were comparable to today's squatter settlements on the fringes of Third World cities beyond the reach of state or municipal authorities.
3. As to planning and regulating the growth of agglomerations, Great Britain set the standard in the early twentieth century, with the two important concepts of the New Town (referred to above) and the 'Green Belt.' The creation of a Green Belt presupposes government control of land use, replacing the market mechanism of the liberal age. Originating in London, Green Belts have also become constituent features of zoning plans in other cities of the former British Empire. The urban development plan of Ottawa shows a Green Belt several miles wide. Persistent urban sprawl caused a characteristic overspill. In the United States too, Green-Belt concepts were introduced into various urban development plans; but in contrast to Europe, the enormous extent of suburbanization could not be contained to fulfill the original purpose of separating urban space from the periphery.
4. In the former Socialist countries, extensive public recreation areas and large private second-home districts exist (neither of these important elements of the periphery of urban regions is to be found in the USA). The public recreation area of Moscow goes back to a Green Belt idea already incorporated in the city development plan of 1935. It is 20–40 km wide and includes major sports and cultural facilities. In most of the big cities of the former USSR, the Green Belt was an integral part of development planning.

Figure 6 The model of a socialist city: Prague. Lichtenberger, E., 1993b. Wien-Prag: Metropolenforschung (Vienna-Prague: Metropolitan Research). Böhlau, Vienna, Cologne, Weimar, ill. 14, p. 102.

Urban Development in the Twenty-First Century

The New Megacities

The increase in world population from around 2 billion humans in 1925 to 7 billion in 2010, favored the growth of mega-metropolises. New global cities also have prominent quaternary sectors (financial, cultural, and political services).

In the foreseeable future, however, twenty-first century city development is unlikely to follow North American models much longer. All over the globe – in the geo-strategically and economically newly relevant BRIC-countries as well as in all countries of the Islamic world – decision makers have recognized that the inherent function of cities, above all of metropolises and capital cities, is unchanged and, with the help of state-of-the-art technologies, has even gained in importance. In these regions megacities with populations of 20 million and more surpass all European and North American metropolises. Two features are typical of them: monumental structures in their city centers are often also social centers and their adherence to the central places system.

It has never been duly recognized that the Chinese urban system has had the longest continuity by far. Already at the time of the Han dynasty (*c.* 200 BC to AD 200) Chinese regional planning authorities devised hierarchies of cities and these cities were considered 'central places' – thereby anticipating what Christaller would present as his concept of central places in 1930.

At the top of the hierarchy are the megacities, with technological infrastructures that often surpass their western models.

Figure 7 Skylines of European, North-American, and Russian million-cities. Lichtenberger, E., 1998. Stadtgeographie (Urban Geography), third ed. Teubner, Stuttgart, Leipzig, Germany. Italian translation: Geografia dello spazio urbano, first ed. Unicopli, Milano, ill. 3.16, p. 198.

The central places hierarchy can also be found in traditional oriental cities. Here, a spatial hierarchy of family, clan, and local quarters is based on family, religious, and ethnic affiliations. The hierarchical organization of living quarters and subcenters is paralleled in the hierarchy of semi-private, semi-public, and public institutions as well as markets (Wirth, 2000–2001).

Twenty-first century megalopolises exceed the scope and feasibilities of democratic urban planning. For 20 years, Martin Seger and his team studied the case of Istanbul and analyzed the complexity of its spatial structuring (see **Figure 8**). This is affected by a variety of factors, such as: political changes; a ribbon development of more than 80 km along the seaside and simultaneous fragmentation of urban satellites; changes in the use of land, e.g., displacement of industries and removal of workshops; developments along the highway to Ankara; construction of the Bosphorus bridges. A special feature of Istanbul is the chain of CBDs from the traditional center, the one-time core of the Ottoman Empire, to the westernized downtown areas. In addition, Istanbul is a model for other megalopolises in developing countries in respect of the upgrading of dwellings constructed over one night (so-called Gecekondu); these cover wide stretches of the periphery and, under existing law, may not be torn down (Seger, 2012).

New Variants of Urban Development in the Western World

Although the arena of twenty-first century urban development has already been moved away from Europe, from the North American countries settled from Europe, and from Australia, to regions which the twentieth century considered 'underdeveloped,' the Western world, too, will witness new variants of urban development.

Changes in the Life Expectancy of the Physical Structure of Cities in Relation to the Life Expectancy of Their Populations

Without being explicitly recognized by the agencies responsible, the relation of urban development to societal changes has altered. Up to the postwar period it was generally accepted as a fact that the life expectancy of the urban fabric was higher than that of their populations. Research into this relationship, however, has shown that this rule is no longer valid (E. Lichtenberger, 1998. Stadtgeographie (Urban Geography) third ed., p. 198). That discovery also reduces the explanatory value of the 'filtering-down' concept of socio-ecological theory, which presupposes a building fabric lasting long enough for several successive cohorts to use it and eventually run it down.

Since the life expectancy of humans increased by more than 30 years during the twentieth century, the curve of the decreasing life expectancy of the physical fabric of cities intersects the curve of the increasing life expectancy of urban population (see **Figure 9**). The point of intersection must be seen as a turning point in the relation of urban development and population development. The period of (intergenerational) changes in the building fabric of cities is ended; a period of recycling of buildings within the lifetime of a generation begins. When exactly this turning point will be reached depends on various factors, including:

- building regulations and zoning laws,
- quality of buildings: materials used and construction technology, and
- socio-economic succession potential.

Figure 8 The Megalopolis Istanbul. Seger, M., 2012. Istanbul's backbone – a chain of central business districts (DBDs). In: Polyzos, S. (Ed.), Urban Development. InTech, pp. 201–216.

Figure 9 Life expectancy of population versus life expectancy of building fabric. Lichtenberger, E., 1998. Stadtgeographie (Urban Geography), third ed. Teubner, Stuttgart, Leipzig, Germany. Italian translation: Geografia dello spazio urbano, first ed. Unicopli, Milano, ill. 4.1, p. 275.

As a rule, the turning point will be reached at different times in different city quarters, depending on the land price gradient.

The consequences of this change may already be seen in North America, where increasing mobility has led to settlements in increasingly peripheral locations. These locations are abandoned as soon as they become outmoded or outdated.

A Dual Cycle Model of Urban Development

In urban research, the theory of cycles, derived from the theory of evolution and first applied in economics, is applied to the problems of producing urban fabric (Lichtenberger, 1991). The concept of urban development is split in two complementary notions: urban expansion and urban renewal, with urban decay (urban blight) being explained as a consequence of the time lag between the two (see Figure 10). A new urban development cycle is started by a change in the political system or in government or in consequence of a major technological innovation. At the other end, a premature or sudden stop to this process will occur only consequent to changes in the political system – examples are the two World Wars and the turning point of 1989. As a rule, such ruptures leave a considerable part of renewal work undone, with unimproved building fabric to be renewed at best in the next cycle. The fact that buildings from different time periods often exist side by side (a fact that in most cases could not be explained by the local situation alone) can be explained by reference to successive urban development cycles in which urban renewal came to a sudden end before the renewal could be completed. As to their relation in time, urban expansion has always preceded urban renewal.

Urban Decay and Urban Renewal in Different Political Systems

A comparison of political systems shows that urban decay is a feature common to all political systems in the Western world and in threshold countries. On the homepage of the London School of Economics, Director Ricky Burdett informs us: "*Fifty per cent of the world's population* currently live in cities, with 33% of city dwellers currently living in slums. By 2020, 75 per cent will live in cities, with *half the world's population living in slums*."

The following is a comparison of the United States and the transforming countries of the EU.

Urban Decay and Urban Renewal in the USA

Apart from the brief period of colonial dependence, urban development in the United States has taken place in a climate of liberalism, i.e., with a real estate market determined by the forces of supply and demand and governed by land prices, land rent, and speculation. Banks and insurance companies invest only when and where they can expect appropriate profits: rundown sections of core cities, being deserted zones, will be excluded from their investment considerations. Thus, urban renewal means either complete clearance of former residential quarters and their designation as traffic areas or a historically or museum-inspired adaptation of attractive parts as living quarters for an affluent new population segment.

Figure 10 The two-stage model of metropolitan expansion and urban renewal. Lichtenberger, E., 1991. Product cycle theory and city development. In: Pumain, D., Saint-Julien, T., van der Haegen, H. (Eds.), Cities in Movement, Urban Systems on the Eve of the 21st Century. Acta Geographica Lovaniensia 31, pp. 120.

The extraordinary amount of new construction, hand in hand with advances in technology, has reduced the life expectancy of residential buildings to one generation. At present, new buildings invade blighted areas faster than was the case 30 years ago. Deserted buildings 'offend' no one, as there is no sense of collective responsibility for the attractive appearance of cities, apart from one's own neighborhood. Government expenditures in the United States have grown consistently over recent decades, but there is relatively little public interest in spending public money on urban revitalization (see Figure 11).

The tax system is a major factor in urbanization. Real estate taxes are the mainstay of local budgets. There is no way out of the vicious circle of marginal populations, small tax yields for local authorities, poor public services (e.g., schools and hospitals), and the physical decay of the building fabric. The indirect effects of the enormous suburban expansion of metropolitan areas are visible in all sectors of the core cities and have resulted in a staggering amount of commercial blight (documented for the first – and the last – time by Brian Berry for Chicago in 1963), of industrial blight, and residential blight.

In the later 1960s, private business became interested in two problems: the renewal of downtown areas and the provision of residential quarters for a new city population. New commercial superstructures were taken out of the public space at the same time. Thus, private interest took over the requisite areas, which had so far been public space. Eventually, three processes were

Figure 11 Decaying residential areas in Philadelphia. Bourne, L.S., 1981. The Geography of Housing. Scripta Series in Geography, London, p. 183; and Lichtenberger, E., 1998. Stadtgeographie (Urban Geography), third ed. Teubner, Stuttgart, Leipzig, Germany. Italian translation: Geografia dello spazio urbano, first ed. Unicopli, Milano, ill. 4.4, p. 288.

set in motion, the results of which are now a distinctive feature of many 'modern' cities:

Malling: Shopping malls have become a way of life in America. There are more malls than cities, colleges, or television stations. Shopping center space has increased by a factor of 12 in the last 40 years (Ashish Kumar Sen, 2005). Malls have become social centers, venues for entertainment, and employment hubs in addition to being centers for shopping (http.//www.nielsen com/en/newswire2013/).

Gating: The privatization of public space in various forms from Watched Neighborhoods in the suburbs to Common Interest Developments, to gated communities, and walled cities.

Privatopia, a combination of Gating and Malling: This is the new ghetto of postindustrial American society with its different life styles; this is the ghetto of a group that excludes itself from the 'city' and attempts to create its own rules and administration, centered in 'pseudo local authorities.'

Urban Decay and Urban Renewal in Postsocialist Countries

Postsocialist cities bear a heavy burden from the time of Communism. Core cities show extensive blighted areas: Private homes had been expropriated and administered by public authorities, but government budgets never sufficed to do both erect public housing (and requisite public transport) on a large scale and maintain the building fabric in the centers. Before

1989, the blighted districts adjacent to downtown areas bore comparison with the situation in the United States, apart from the fact that defective building fabric was not met with social marginalization.

After 1989, however, a sort of 'New Founders' Period' began. Privatization of real estate is a major consequence of liberalization; thus the functioning of city centers has become a major objective of urban planning (Lichtenberger et al., 1994).

The Locations of Office Quarters in the USA and in Europe

In North America the office sector is the offspring of business while in Europe it rests on two additional pillars: the demands of government and administrative agencies and of semiofficial institutions. As to the quarters chosen for office buildings, America and Europe differ substantially. North America has been the trendsetter of economic globalization. After World War II skyscrapers became the typical buildings of the metropolitan downtown. But Chicago's Sears Tower, erected in 1974, is nearly synchronous with starting the suburbanization of its office sector in 1975 as the last step in the suburbanization of private homes as well as of industry and business. After industrial parks came office parks and Edge Cities (Garreau, 1991). A case in point is Washington, with 16 major edge centers recently constructed. In consequence of such relocations, more than a quarter of the office spaces available in downtown areas have been deserted (see **Figure 12**).

Developments in Europe have been quite different. There, the construction of metropolitan subcities initiated by public planning (e.g., La Défense in Paris, the City Nord in Hamburg, or the UN City in Vienna) has met only a fraction of the demand. Nor do office buildings erected by big corporations make up more than a fraction of the total supply of office space (**Figures 12** and **13**).

In Europe, the construction of office towers lagged one generation behind North America. They are not located in traditional downtown areas, but rather at the edge of built-up spaces. In all compactly built-up continental cities the conversion of private apartments into offices is still a considerable factor in the creation of office space. The suburbanization of the office

Figure 12 The model of downtown and edge cities in US metropolitan areas. Lichtenberger, E., 1998. Stadtgeographie (Urban Geography), third ed. Teubner, Stuttgart, Leipzig, Germany. Italian translation: Geografia dello spazio urbano, first ed. Unicopli, Milano, ill. 2.5, p. 48.

Figure 13 The changing logo of Syracuse from an industrial to a leisure city. Lichtenberger, E., 1998. Stadtgeographie (Urban Geography), third ed. Teubner, Stuttgart, Leipzig, Germany. Italian translation: Geografia dello spazio urbano, first ed. Unicopli, Milano, ill. 5.8, p. 334.

sector has now advanced as far as the Trade Centers next to international airports. Edge cities are nowhere in sight.

From the City of the Labor Oriented Society to the City of the Leisure Society

Urban planning in Europe is based on the organizational model of a labor oriented society, with the most important functions of the tertiary and quaternary sectors to be discharged in the city center. In recent decades, however, the organizational model of a consumer society has come to the fore, at least in North America, where the consumers are responsible for the takeoff of suburbia.

By now, the city of the consumer society is being rivaled by the city of the leisure society. Wherever it was newly established, like in Florida and California, later in France, in the Alps and around the Mediterranean, this type of city depends on favorable climatic conditions. At present European countries tend to locate their leisure societies in rural areas – with the effects of causing rhythmical over-crowding and desertion of the countryside in the course both of weeks and years. While the labor society depends upon the redistribution mechanisms of the welfare state as to its organization and financing, the commercialization of leisure takes place in a near-perfect capitalist system. By way of direct and indirect government subsidization of the tourism industry, today's leisure society is actually subsidized by the labor society, i.e., by the gainfully employed: e.g., by concessionary rates in public transport or accident insurance services.

Among the most recent developments is "city marketing," a consequence of the discovery that not only the *ville festivale* offers a considerable potential of commercialization in the steadily growing city tourism. The idea is that of marketing the image of a city as an export article. Subsidized by the French government, Paris constructed the event city "Eurodisney" as part of the *agglomération*. In North American metropolises one finds examples of event cities offering all sorts of entertainment, catering and fun. There are also examples of employing a city's "logo" in state-of-the-art advertising (see **Figure 13**). The recreational quality of a city for its own inhabitants is not affected as long as a temporal and spatial separation of residents and foreign leisure population is possible (motto: "When the tourists come, the Romans leave their town").

Cities Under Postsocialism

Abstract

In postsocialist cities, urban environments formed under socialist regimes are being adapted to new conditions shaped by the transition to capitalism. With the establishment of market rules and pluralistic democracy, social practices of individuals, firms, and governments became imprinted in urban landscapes. Urban change has been especially influenced by internationalization, economic restructuring, social differentiation, postmodern culture, and neoliberal political practices. The main transformations in the spatial organization included the commercialization of city centers, the dynamic and spatially selective revitalization in inner cities, and the radical transformation of suburban hinterland affected by sprawl.

Introduction

This article discusses urban change in postsocialist cities. The term postsocialist refers to societies which had been prior the revolutions of 1989 known as 'socialist' and which have been since 1989 undergoing transformations toward capitalist societies with market-based economy and pluralistic democracy in political decision making. While the former socialist and so called 'second' world (Andrusz, 2001) included countries on most continents, this article mainly builds on the experience and situation in major capital cities of postsocialist Central and Eastern Europe, since these are the cities that have been studied the most. The generalization based on these cities may also be relevant for other postsocialist cities.

The city is understood as complex dynamically evolving sociospatial formation. It is internally differentiated and structured not only in terms of social, economic, or political differences between individuals and social groups, but especially in terms of local sociospatial formations such as residential neighborhood including ethnic enclaves of immigrants, gated communities of better off population, middle-class suburbs, or ghettos of socially excluded, as well as functional zones such as industrial areas, office districts, shopping, and entertainment nodes. The city is also integrated through interaction between people, firms, and organizations, between residents, entrepreneurs, and politicians, and, as these actors are spatially embedded, also between local sociospatial formations integrated into an urban region.

This article is focused on urban change, on processes through which the city and places within urban space are produced, reproduced, and transformed. It emphasizes relations between social processes and spatial structures via social practices. In established societies, the social practices are guided by a set of broadly accepted rules. The unfolding daily life framed within relatively stable institutions results in relatively stable spatial patterns. The correspondence between social institutions, social practices, and structures and spatial arrangements might gradually change in the course of ongoing evolutionary social processes, such as transition from Fordism to post-Fordism, industrial to postindustrial society, and social to neoliberal state or during second demographic transition.

However, the evolutionary relatively gradual processes of urban change may be interrupted by periods of radical urban restructuring influenced by turbulent revolutionary transformations in political and economic principles of societal organization. This is the case of postsocialist cities, where the institutional setup was radically changed in the 1990s. The capitalist political economy leads to distinctively different social practices and urban spatial organizations. Contradictions between the inherited socialist urban patterns and newly established capitalist rules created tensions resulting in the restructuring of existing urban areas and the formation of new postsocialist urban landscapes (Sýkora, 2009). Even though the principles that influence the production of urban environments were changed quickly, the pace of change in the built environment, land-use patterns, and residential differentiation is much slower. The urban transformation of postsocialist cities is an unfolding process that may take decades. Revolutionary transformations in urban spatial organization, such as dynamically developing sprawl and increasing residential segregation, pose significant challenges. They call for anticipation of future developments and critical engagement in debating urban change.

The postsocialist cities offer a chance to trace the impact of transformations in political and socioeconomic forces and changing social practices on the logic of urban space generation under the condition of revolutionary, radical, and rapid transformations framed by the transition from communist totalitarian to democratic political regimes and from command to market economies. We can not only compare how two distinctively different societies of socialism and capitalism produce their own urban spaces, but in an online perspective observe how capitalism appropriates and reconstructs the former patterns to its own needs.

There is a widespread recognition of the diversity of urban transformation in former socialist countries indicating that different postsocialist trajectories may be developing (Tosics, 2005). Differences have emerged between the countries that have managed to apply more comprehensively the Western concept of capitalism, and those whose development is more based on the locally specific recombinations of selected aspects of socialism, capitalism, and unique features that have emerged during postsocialism. However, the rejection of communism and the acceptance of capitalist features have placed the postsocialist societies, countries, and cities on a similar trajectory leading away from communism and toward various forms of

capitalism. In this article, while acknowledging the contextual embeddedness of urban transformations and their consequent local specific features and trajectories, the general and common features developing under the imperative of globally spreading capitalism will be highlighted.

The article starts with the reflection of the trajectories, patterns, and underlying forces of urbanization under socialism. This is followed by a section that overviews the recent transformations toward capitalism, juxtaposing two different political and economic systems with their own logic of urban space generation. Specific attention is devoted to relations between socialist legacies and global capitalism in shaping postsocialist urbanization and to major challenges that postsocialist cities face on their transformation path.

Socialist City

The studies of cities in Central and Eastern Europe suggested that a socialist city existed as a specific entity different from cities in developed capitalist world (French and Hamilton, 1979; Smith, 1996). However, while some scholars emphasized the specific nature of socialist urbanization referring to distinctively different socialist and capitalist political and economic systems (Szelenyi, 1983), others advocated similarities between urbanization in socialist and capitalist countries highlighting the universal influence of industrialization and modernization (Enyedi, 1996). While we can accept that both socialist and capitalist cities were variants of a more general twentieth century modern urban development, important features, such as lower levels of urbanization, less urbanism, and distinct urban spatial structure (Hirt, 2013), distinguished cities in socialist and capitalist countries.

Similarly to capitalist cities, the socialist city was shaped by cultural modernity, industrialization, technological progress, and advanced division of labor. However, the particular character of socialist political and economic organization mediated through the state planned distribution of resources and planned urbanization (Musil, 1980; Smith, 1996) yielded new economic, social, and territorial patterns. They included the lower share of services and higher share of industries in terms of employment and land use, sociospatial disparities specific to socialist production and allocation of housing, and a more compact urban morphology in comparison with capitalist cities. Under the condition of modernity, socialist cities represented the major alternative to capitalist urbanization.

The built environment, land use, and segregation patterns in socialist cities were shaped by political and economic forces that were radically distinct from capitalism. The socialist regime claimed to attain a socially just society with economy serving wider population needs. The essential starting point in forming socialist societies was the elimination of private ownership of means of production and market allocation of resources, which were seen as the key mechanisms being responsible for producing social inequalities. The essential aspects of the socialist system were the common ownership of the means of production and the administrative allocation of resources overseen by the state authorities guided by the power of Communist parties. The flow of resources between governments, firms, and households was regulated by the top-down hierarchically organized system of central planning. The economic growth shall guarantee an ever-increasing quality of life and socially equitable distribution of resources. However, the priority given to production and strategic (mostly heavy) industries, led to the underdevelopment of consumer services. The inefficiencies of central planning, especially its low capability to stimulate innovations, resulted since the 1970s in exhausting inner resources and slowing down economic and social development.

The industrialization of the socialist economy was at the nexus of development priorities. It led to the boom of urban industrial centers that attracted rural migrants pushed away from their villages by the collectivization of agricultural land and the mechanization of agricultural production. As a result, the socialist countries experienced a fast growth in their levels of urbanization. However, the growth of urban jobs was not paralleled by a corresponding supply of new housing. A significant portion of the rural population employed in cities retained their rural residence leading to an increasing share of rural residents commuting to cities, using mass public transit systems. The phenomenon of discrepancy between the urbanization of jobs and housing was described as under-urbanization (Murray and Szelenyi, 1984; Szelenyi, 1996).

Socialist cities and their metropolitan areas were managed through the top-down centralized control of territorial development as a hierarchically organized system. With land development under the control of state authorities, government policies concentrated the spatial allocation of public investments and thus urban development in few target areas. First of them was the expansion of industrial capacity by the development of new and the extension of existing industrial zones stimulated by the preference of production over consumption and political goal of keeping manual workers as the revolutionary force in major cities. Second, the construction of massive housing estates at the urban edges provided standardized supply of new housing. Third, a dense network of public transportation was developed to assure effective commuting between places of residence, work, services, and leisure activities. Fourth, services were provided in hierarchically organized system of neighborhood, district, and city urban centers, in order to guarantee economies of scale as well as even accessibility by population. Finally, city centers were redesigned as monuments of the social and economic prosperity achieved under the leadership of ruling communist parties.

Although central areas concentrated retail and other consumer services, they did not resemble the picture of capitalist urban downtowns dominated by commerce. In societies governed by central planning machinery, there was no room for financial and other business services. Similarly, the state organized supply of basic and standardized good has not required the development of retail and other consumption-oriented services on the scale known from capitalist societies. Consequently, socialist city centers retained substantial proportion of residential function. The political strategy to keep manual workers as the revolutionary force in major cities as well as nonexisting market pressure on a more economically efficient utilization of land purposefully maintained a higher share of industry in terms of both employment and land use within cities. Industrial areas penetrated from old inner city

quarters to newly established outer city zones. Sections of the inner city presocialist neighborhoods decayed due to the disinvestment of the state whose prime concern was to build new socialist areas. Renewal programs applied in last two decades of socialism often led to brutal redesign of presocialist inner-city landscapes. The majority of new construction concentrated at city edges in high-density residential areas of multistory apartment buildings and new industrial zones. In a contrast to sprawling North American and West European metropolitan areas, the socialist cities developed without suburban residential areas and nonresidential ribbon developments typical for capitalist urbanization. The extent of urban industrial land use and the scale of housing estates constructed for several thousands of inhabitants, and the consequently high proportion of industrial labor force and multiple-family housing noticeably distinguished the socialist city from the capitalist city.

Population in urban space was primarily differentiated by its demographic characteristics (Musil, 1987). The urban landscapes build under socialism looked like a mosaic of relatively large housing estates each containing particular age cohort of population with similar positions in family and life cycle. The formation of such pattern was conditioned by the state financed housing construction, which was spatially concentrated in large districts built-at-once, by the administrative allocation of dwellings to young families with children at the start of their family and housing career, and low levels of overall migration after retaining first housing. Particular generations of housing estates corresponded with certain age cohorts of population. Despite the low level of residential socioeconomic differentiation, sociospatial inequalities existed due to the access of people with higher societal and communist party merits to better housing. Large areas, characterized by social mix of households and less segregated and more evenly distributed homes of working class population, were contrasted with socialist elites concentrated in few exclusive neighborhoods. In general, the socioeconomic status declined from city centers toward urban hinterland, with the exception of higher social status of some well-located new housing estates. Most socialist countries were ethnically homogeneous and with the exception of Roma concentrations, ethnic differentiation was not a distinguishing feature of urban social landscapes. However, in the cities within the Soviet Union, the sociospatial pattern was more complex due to the migration of ethnic minorities within USSR (Smith, 1996).

City in Transition: Postsocialist Urban Transformations

Since the collapse of communist regimes in Central and Eastern Europe, cities in the former socialist countries have entered a period of dramatic reconfigurations. In the 1990s, these countries abolished socialism and set on the path toward capitalism with democratic governments and free markets. The installation of market rules and pluralistic democracy began to change social practices of individuals, households, firms, organizations, and governments leading to the development of new social processes reshaping social structures that have been for decades moulded by the socialist regime. The social changes became imprinted in urban landscapes bringing dynamic sociospatial reorganization of former socialist cities. Urban environments formed under the socialist system have been adapting to the new circumstances generated by the political, economic, social, and cultural changes associated with the transition to capitalist market economy and democratic political regimes (Enyedi, 1998; Hamilton et al., 2005; Tsenkova and Nedović-Budić, 2006; Stanilov, 2007).

In the 1990s, former socialist countries abolished socialism and set on the path toward the establishment of capitalism with democratic governments and free markets. The process of societal change is generally referred to as the postsocialist transition. The term transition has been initially associated with the neoliberal agenda of shock therapy, based on the radical replacement of the basic political and economic institutions of socialism with democratic and market arrangements. However, a number of experts have responded to the visions and rhetoric of neoliberal designers of the transition pointing to path dependencies and impacts of socialist legacies (Nielsen et al., 1995; Pickles and Smith, 1998). Using the term transformation they accentuated continuities and highlighted the hybrid nature of postcommunist realities with respect to the recombination of socialist and capitalist elements as constituents of the new postcommunist society (Stark, 1996). This body of work has contributed to the realization that postcommunist transition is not a simple replacement of one social system with another, and that real-life transformations include not only new social forms but also a recombination of new and old elements. The postsocialist transition is now commonly understood as a broad, complex, and a lengthy process of social change (Herrschel, 2007).

The radical change in the political and economic setup has stimulated transformations in virtually all spheres of societal development with its imprint into changing urban structures. The notion of postsocialist city has provided an umbrella concept for insights into urban restructuring stimulated by the government reforms of the 1990s. Two decades since the collapse of former Communist regimes, the relevance of postsocialism began to be put into question. However, while systemic institutional transformation may be over, postcommunist cities are still very much undergoing transformations in their built environment, land-use, and sociospatial patterns (Sýkora and Bouzarovski, 2012). The issue is whether the processes of urban change, such as gentrification or suburban sprawl are new forms of neighborhood change and city development under capitalism or whether they are related to the adjustments of inherited socialist urban legacies to new societal conditions. As the development of these processes is stimulated by structural deficiencies produced under socialism that has sprung up with the establishment of capitalist market economy, they should be interpreted as an integral part of the overall postsocialist transformations.

Transformations take place at many levels and include processes occurring at different speeds (Sýkora and Bouzarovski, 2012). While the systemic institutional transformations have been relatively fast, the pace of changes in social practices has been much slower. The complex environmental systems of cities and urban regions, which embody not only social institutions and practices but also physical artifacts,

have the longest time-span of change and persistence. Distinguishing three levels of postcommunist transition: "*i*) the institutional transformations that created a general societal framework for transition, *ii*) transformations of the social, economic, cultural and political practices exhibited in the everyday life of people, firms and institutions and resulting in social restructuring, and *iii*) the transformation dynamics of urban change"; Sýkora and Bouzarovski (2012) argue that: "The key aspect for understanding post-communist urban change is the distinction between the short-term period when the basic principles of political and economic organization are changed, the medium-term period when peoples' behaviors, habits and cultural norms are adopted to a new environment and transformations in a number of spheres and begin to effect broader societal change, and the long-term period in which more stable patterns of urban morphology, land use and residential segregation are reshaped."

In the first years of the transition, the leading force of transformations was played out by systemic government-controlled reforms that aimed to establish a capitalist system based on a pluralist democracy and a market economy, and to integrate socialist countries into global capitalist economy. The establishment of democratic political system with free elections and the plurality of political forces was followed with economic reforms aimed at the introduction of market system through the privatization of state assets, the liberalization of prices and free foreign trade relations. These reforms were necessary preconditions for other societal transformations to take place through the changing practices of firms and people in turn reflected in changing economic, social, and cultural environments. Urban change has been especially influenced by internationalization and globalization, economic restructuring in terms of deindustrialization and the growth of producer services, increasing social differentiation, new modes of post-modern culture, and neoliberal political practices (Sýkora, 1994; Stanilov, 2007).

International companies and foreign direct investments became leading agents in reshaping local economies and urban geographies. Foreign investment in real estate reflected the demand for space generated by international firms in producer and consumer services as well as in industrial production and started radically reshape urban landscapes and skylines. Foreign managers and high-salary employees as well as low-paid immigrant workers formed new mutually polarizing segments of population on the housing market. Deindustrialization, which presented the downward side of economic restructuring, has been in many placed counterbalanced by the growth of new industries and consumer services. However, both offering mostly low paid-jobs. Only major urban centers, usually capital cities, benefited from the growth in advance producer services. Economic change mediated through labor markets was expressed in increasing wage and income disparities that contributed to social polarization among households, formation of new sociospatial formations, and increasing territorial disparities. Social inequality and conflicts appeared in initially, socially, and ethnically homogenous urban societies.

New conditions allowed for the development of a greater plurality of values, with particularly strong tendency toward individualism and promotion of self-interests. This impacted not only rapid decline of family formation leading to aging urban populations but especially rapid proliferation of consumption oriented life style. National and urban governments often pursued political strategies grounded in a neoliberal discourse, which saw free, unregulated market as the mechanism of allocation of resources that would generate a wealthy, economically efficient, and socially just society. While the state was perceived as the root of principal harms to the economy and society, urban transformations have often been left to the operation of free market partially bound within the framework of traditional rigid physical planning instruments. In such constellation, powerful investors have often steered politicians and planners to facilitate urban development in a manner favorable to capital (Altrock et al., 2006; Horák, 2007)

In postsocialist cities, the urban environments inherited from socialist era, have been adapted to the new conditions created by government reforms and ensuing economic, social, and cultural transformations. With the introduction of capitalist urban economy, the contradictions between capitalist rules of the game and socialist urban environment led to the restructuring of the socialist urban features and structures and the formation of new capitalist urban landscapes. Most urban growth and change concentrated in city centers, selected inner city nodes and areas, and in rapidly expanding suburban zone (**Figure 1**).

First years of transition were characterized by the rapid commercialization and physical regeneration of expanding city centers accompanied by the decline of residential functions, densification of land uses, traffic congestion, and conflicts with historical heritage. In the course of time, urban change spread to inner city areas, which have been affected by both growth and decline. Deindustrialization left behind extensive brownfields, which presents not only the threat of decline but also potential for redevelopment. Urban restructuring was driven by the replacement of inherited land uses with new and economically more efficient activities. In major cities, new commercial growth concentrated in out-of-centre office clusters and retail and entertainment complexes. Besides the formation of new secondary commercial nodes and ribbon development areas along highways, waterfronts received particular attention of development industry.

The shifting housing preferences placed many socialist housing estates and some older presocialist neighborhoods on downwards spiral. On the other hand side, gentrification began to bring some inner city quarter to their former glory and prestige. Together with newly constructed condominium districts and gated residential areas reflected desires of new middle classes to live apart. Considering the formation of immigrant enclaves and ghettoization of Roma and socially vulnerable populations in housing estates in declining old industrial cities, the new residential landscapes began to exhibit bold segmentation in housing supply and evolving segregation processes. With the increase in personal wealth of population, people started to move to urban hinterlands to fulfill their dreams of single family home. Sprawling residential districts have been accompanied with big-box retailing, warehousing, and industrial districts located along highways and on their major intersection. Suburbanization has become the most dynamic process changing the landscapes of postsocialist city regions (Stanilov and Sýkora, 2014).

Global Capitalism, Socialist Legacies and Challenges of Postsocialist Urbanization

One of the key debates in postsocialist urban studies has been evolving about the issue of interaction between socialist legacies and neoliberal capitalism. Gentile et al. (2012) coin the term heteropolitanization referring to increasing internal urban complexity and heterogeneity of postsocialist city characterized with the simultaneous emergence of new social and spatial patterns in an environment, where powerful legacies preserve the patterns inherited from the previous era" (Gentile et al., 2012: p. 297). Golubchikov et al. (2013) emphasize the "mutual embeddedness of the legacies of socialism and the workings of neoliberal capitalism that jointly produce … the hybrid spatialities of transition" (Golubchikov et al., 2013: p. 618). They go in their argument even further speaking about "the subsumption of the inherited systems into the very logic of capitalist and neoliberal relationships, so that, while capitalist practice feeds on the legacies of state socialism, it also alienates them from their history to make them the infrastructure, and often the agency, for its own expansion" (Golubchikov et al., 2013: 630).

The postsocialist developments bring the re-emergence of some presocialist patterns, transformations in some areas from socialist times and creation of new postsocialist urban landscapes. While the present urban patterns can be interpreted as hybrid (Gentile et al., 2012), in the course of time, new capitalist urban developments will be gaining even more important role in the overall urban organization. Postsocialist city shall be seen as a temporary phenomenon existing in the time-period between the institutional reload through the replacement of the socialist with the capitalist rules of the game and the completion of corresponding transformations in urban built and social environments (Sýkora, 2009). While many features resembling socialism will certainly remain present even in distant future, the essence of daily urban life and city operation will be capitalist.

The dynamic development of suburbanization, a boom of gated communities and gentrification of inner city quarters, the emergence of socially excluded localities and enclaves of immigrants, the establishment of office parks and shopping districts, all are linked with the expansion of capitalism to former second world countries. These similar forms of urban developments, nowadays observable across the globe, are the results of the social practices of firms, households, and governments under the political, economic, and cultural conditions of globally spreading capitalism. Global capitalism has been the most powerful agent in the spread of similar urbanization trends and features across the former socialist countries of Europe, as well as in many other regions around the world. The impact of global capitalist forces on postsocialist urban change is, nevertheless, far from uniform. While the global capitalist system embraces nearly the whole planet, individual countries, regions, cities, and neighborhoods are integrated into it in a highly uneven manner. In postsocialist countries, the legacies of socialism, the character of new capitalist institutional setup, the size and attractiveness of market, etc. produce internally differentiating local outcomes of global capitalism.

The most distinguishing feature of local postsocialist urban restructuring under the imperative of global capitalism is the spatial selectivity of investments and territorially uneven growth. The desire of capital to utilize profit opportunities has not been counterbalanced by public sector striving for more socially and territorially balanced development. The urban development in the postsocialist cities has been managed through a mixture of free market practices of private firms struggling for their share of newly emerging markets and a highly decentralized, locally based, and regionally uncoordinated system of land development in city regions.

Rapidly developing suburban sprawl and residential segregation are two key processes of uneven development in postsocialist cities, symptomatic features of global urbanism spreading across former socialist countries and, at the same time, major challenges for public policies. Residential and commercial activities have decentralized into cities' hinterlands and radically transformed the compact physical morphology of the former socialist city. The dynamics of population and job growth in new suburbs has been remarkable bringing city regions in postsocialist countries among the most sprawling

areas in Europe (EEA, 2006). Suburbanization has increased the range of housing options for the middle and upper income households and brought employment and shopping opportunities closer to residents living in the hinterland of cities. At the same time, sprawl, which has become the typical form of postsocialist metropolitan growth, has undermined the prospect of achieving smart, inclusive, and sustainable development. Suburban growth is rarely recognized as an integral component of the overall process of metropolitan development, leaving it to the decisions of numerous suburban municipalities competing for their stake in the circuits of real estate investments and population flows.

The simultaneous growth of gated communities, gentrified areas, and suburbs of wealthy on the one hand side, and the degradation of some housing estates, formation of socially excluded localities, and spatial concentrations of immigrant workers, reflect tendencies toward segregation and the emergence of sociospatially polarized city (Hirt, 2012). Surprisingly, the level of sociospatial inequality has not increased during the first decades of capitalism (Marcinczak et al., 2013). While inner city gentrification and suburbanization of middle class is lifting up these residential zones from below average social status, socialist housing estates that under socialism concentrated younger and better-educated population are declining from their better-off position toward city average. The simultaneous operation of segregation processes and decline in sociospatial disparities is a temporary paradox of postsocialist transformation. In the course of time, the capitalist urban economy accompanied with neoliberal practices of urban development will strengthen and expand the new localities that concentrate populations from the opposite sides of social spectrum and capitalist segregation will definitely erase socialist legacies.

The emerging social urban problems call for the reconsideration of urban and regional planning, policies, and practices pursued since the early 1990s. The postsocialist governments placed high priority on individual choice, economic freedom, and private property rights, without recognizing that urban development is not just a matter of personal but of societal choice. Fighting suburban sprawl and residential segregation requires the coordination of urban development at the metropolitan level and in interscalar coordination with national and local governments. However, the stronger role of governments in social and territorial development has been resisted.

Conclusions

Postsocialist cities are cities under transformation. Urban landscapes formed under socialism are being adapted and remodeled to new conditions shaped by the political, economic, and cultural transition to capitalism. The development of cities in former socialist countries is now largely governed by market forces and democratically elected governments. However, the reorganization of urban landscapes in postsocialist cities that began with the reforms of the 1990s has not been completed yet. "Their defining feature remains the incessant and relentless process of structural transformation that has started to unfold since the end of communism" (Sýkora and Bouzarovski, 2012: p. 44).

Even though the series of political and economic transformations is already two decades old, the postsocialist transition is a project still not finished. At present, sprawl and segregation dramatically reconfigure urban landscapes. These urban developments can be seen as outcomes of present day choices that will impact the development of society for decades to come. Postsocialist societies are still facing critical junctures. Unfortunately, negligible attention is given to the anticipation of future developments, their critical evaluation, and the discussion of alternative development paths. Postsocialist developments can lead to the formation of new path-dependent lock-ins that these societies will later regret (Sýkora, 2008). They can learn from analogical developments and alternatives known from other countries and pay attention to the problematic developments that may be avoided if alternative development paths are taken sooner rather than later.

Citizen Journalism

Abstract

Citizen journalism refers to nonprofessionals taking an increasingly central role in news reporting, writing, editing, publication, and distribution. These roles are exercised both within news organizations and outside them. Studies of citizen journalism are commonly structured around a distinction between citizens and professionals, with the key issue being to what extent citizen journalism fulfills the promises of normative liberal–pluralist press theory.

Citizen journalism refers to nonprofessionals taking an increasingly central role in news reporting, writing, editing, publication, and distribution. These roles are multiple and variable, as Nip (2006) suggests in an influential typology. Although emerging primarily in the West, citizen journalism lays claim to being a global phenomenon; its Western roots have been extended and remade through countless instances in many parts of the world (Allan and Thorsen, 2009). It is part of a global reorganization of media work (Wunsch-Vincent and Vickery, 2007).

Citizen Journalism and the Profession

Citizen journalism draws its significance from a contrast with and resulting criticism of professionalized journalism. General acknowledgment of journalism as a profession aspiring to the same status as practitioners of medicine and law dates in England with the formation of the Chartered Institute of Journalists in 1884 and in the USA from the teaching of courses in journalism in the nineteenth century and by the early-twentieth century the establishment of schools of journalism in universities (Chartered Institute of Journalists, 2012; Schudson, 1978: p. 152).

Recognizing that citizen journalism gains its relevance by being distinguished from professional journalism emphasizes that its core claim is related not to an expansion of participation so much as its challenge to professionalization. The significance of citizen journalism comes from nonprofessional nonemployees taking an increasingly central role in a heretofore professional activity, thus challenging the exclusivity and authority of professionalization itself. Indeed, an institutionalized distinction between a professional class of writers and their readers/consumers can be traced to the beginnings of commercial media production (Hamilton, 2008: pp. 50–53). Forms in which nonprofessionals have routinely been engaged in professional media include as readers, listeners, and viewers; as buyers and subscribers; as contributors of letters, comments, and opinions; and as sources, subjects, and contestants (Griffen-Foley, 2004).

Despite its usefulness, this relatively unproblematic definition is quite complex in practice. One key reason is the multiple positions from which the challenge to professionalization is based. Challenges of citizen journalism emerge from both outside and inside established news organizations (Atton and Hamilton, 2008: pp. 63–76). On one hand, people outside of journalism industries see citizen journalism as a critique of the restrictions and privileges of professionalism and of the insulation more generally of journalism from its readers and society. On the other hand, citizen journalism is also practiced inside as part of management-sanctioned strategies of economic revitalization. For many publishers, managers, and other professionals, citizen journalism can help rescue the professionalized commercial model of news production that has been a dominant form in the West for more than 150 years.

A second key reason for the complexity is that the multiple locations of these challenges are not opposites. Each draws upon the other for its own claims of legitimacy and authority. On one hand, citizen journalism as fostered and practiced outside established news organizations (such as by bloggers and activists) emphasizes its greater professionalism. This is often expressed in claims to greater 'quality' and 'objectivity' compared with underfinanced, deadline-obsessed commercial news organizations that too often simply rewrite public-relations press releases. From this point of view, the problem to which citizen journalism is a response is sloppy unprofessionalism or manipulation by publishers or advertisers.

On the other hand, citizen journalism as fostered by and within established news organizations emphasizes its ostensible democratization of news production. This is often expressed via liberal Anglo-American media traditions as a way to restore the ostensible 'marketplace of ideas' by encouraging the wider diversity of participants and views it requires (Altschull, 1990). From this point of view, the problem to which citizen journalism is a response is insular preoccupation with immediate financial success and over-professionalization (McChesney and Pickard, 2011).

Internal and External Critical Positions

What became citizen journalism emerged through a series of developments and forms spawned by both internal and external critiques. Internal critiques took issue with the abrogation of social responsibility inherent in the disconnection of insulated professionals from the readerships/communities they were to serve.

During the 1960s, significant criticism of the professional convention of journalistic objectivity took place in the form of the so-called 'New Journalism.' This form of reportage

repositioned the reporter, but, unlike citizen journalism, left the reader/viewer's position untouched. Also referred to as 'literary journalism,' such writing placed the reporter as a character, if not the main character, in the story rather than as an outside, neutral observer and recorder (Hollowell, 1977; Weingarten, 2006). 'Participatory journalism' was how the work of author George Plimpton (1966) and documentarian Jon Alpert was described, although not without criticism due to not adhering to the professional form of objectivity (Dickey, 1977; Alter, 1986).

Yet, the new, literary journalism quickly became a global phenomenon (Bak and Reynolds, 2011). By the mid-1990s, additional criticism of professionalized, routinized journalism emerged from within the news industries. In a search for how to make news a more compelling product and perhaps better fulfill its role of empowering citizens to make more-informed choices, efforts emerged to involve readers by making the reporting process more transparent and thus open to public scrutiny. A significant, early effort was the *San Jose Mercury News* experiment with reporter Gary Webb's series 'Dark Alliance' on a CIA-crack cocaine connection (Webb, 1996; the book-length report is Webb, 1998). In the online stories, links allowed readers to view reproductions of a great deal of documentary evidence on which the reporting was based. The hope was that doing so allowed readers to make their own assessment of the veracity and legitimacy of conclusions drawn. The series was subjected to great hostility by the news industry, with the online version coming down and Webb's firing from the *Mercury News* (Webb, 1998: pp. 437–466; Webb, 2002; Paterno, 2005).

By contrast to expanding the writing style of journalism, other industry-centered efforts saw in citizen journalism a viable business strategy for addressing declining readerships. Such efforts built upon pre-Internet projects such as 'public journalism' and 'civic journalism' in the USA (Rosen, 1996; Black, 1997). By 2005, the industry recognized the general trend toward citizen journalism, recognizing it as largely a US and UK phenomenon, although present in other countries (Jesdanun, 2005). Unlike the aspiring national and international reach of citizen-journalism efforts outside of the industry, industry-centered efforts took shape as a hyper-localized form of commercial community journalism (an early US description is Oxfeld, 2005). While this can be seen in other countries such as England in which private ownership and commercial support forms the bedrock of the system, it is most prevalent in its development in the USA (Roberts, 2006). By the mid-2000, the increasing availability and diffusion of consumer-grade digital cameras (and, later, smartphones with video capability) enhanced the attraction of citizen journalism for television-news organizations, which not only used amateur footage more frequently, but also formulated for amateurs online basic training in visual journalism (Romano, 2005).

External critiques took issue with the selectivity and skewed nature of news coverage, which contradicted the professional ethos of impartiality and comprehensiveness. In doing so, they built upon press criticism from its earliest days (McChesney and Scott, 2004; Theobald, 2004; Goldstein, 2007).

The late 1990s brought new capabilities for social movements to address global audiences entirely outside the sphere of corporate news media. Following on the heels of various forms of community and citizen media, ranging from public-access cable channels to a community-run satellite distribution system, Independent Media Centers were established to provide grassroots viewpoints and information during the Seattle meeting of the World Trade Organization in 1999 (Howley, 2005; Halleck, 1993; Hamilton, 2008: pp. 121–159). Its innovation was to create a system of open-publishing, whereby individuals could upload to the website their own news stories and video, for viewing by potentially anyone worldwide (Kidd, 2003).

Developments in the 2000s brought together all these disparate aspects. Additional digital platforms, such as the website Blogger, soon emerged and allowed self-publishing and worldwide distribution in a form far less technical than had previously been the case. New amalgams of professional and nonprofessional news organizations, such as in 2000 the South Korean organization *OhMyNews*, emerged which exemplified a challenge to the mainstream media regime of that country by creating a sustainable hybrid non-professional/professional commercial news organization (Kim and Hamilton, 2006). Proto-national and international systems in addition to Independent Media Centers emerged by late 2004, in such examples as Wikinews (Glasner, 2004). The progressively greater integration of social media such as Facebook and Twitter into not only the organizing of social movements, but also of legitimate reporting, has only furthered these trends (Heflin, 2010).

Postpositivist Studies

Postpositivist studies of citizen journalism search for a means of codifying stable and predictable relationships (Greer, 1969). The typical research design is comparative, in which professional journalism and citizen journalism are compared directly or indirectly in terms of how well each lives up to the normative roles attributed to journalism by Anglo-American liberal theories of the press (Siebert et al., 1956; Altschull, 1990).

One common method of quantitative content analysis seeks to determine whether and to what degree citizen journalism exemplifies the liberal–pluralist normative goal of journalism of providing the broadest range of views and opinions. Examples include Carpenter (2010), which found in a comparison of coded news items that the range of diversity was greater in citizen journalism than professional journalism. Lacy et al. (2011) sought to determine whether and to what degree online citizen journalism was capable of substituting for professional journalism in the economic marketplace. Upon coding the content of online publication websites, they found that "citizen news and blog sites can serve as complements to daily newspapers," thus posing little economic threat to professional news organizations (p. 44).

Research surveys also focus on whether and to what degree citizen journalism fulfills the normative role attributed to the press by liberal–pluralist philosophy. Kaufhold et al. (2010) address the issue of whether online user-generated news informs the public in the same way as professional journalism does. While consumption of user-generated journalism was negatively related to political knowledge but positively related to participation online and off-line, consumption of

professional journalism was positively related to political knowledge and only to off-line participation. Nah and Chung (2009) found in their survey of newspaper editors that they rated the importance of professional journalism more highly than citizen journalism. And Robinson and Deshano (2011a) sought to determine the motivations of people who engaged in citizen journalism. Among other findings, citizen journalists were found to gain a host of positive affective benefits through their participation.

Functionalism

Similarly to postpositivism, a functionalist perspective also concerns itself with a comparison of professional journalism and citizen journalism in the degree to which each fulfills its normative role in a democratic society. While organistic conceptions of society as a set of interrelated systems and functions date from the earliest years of social theory, they were applied to mass communication research initially via the formulation of US political science scholar, Harold Lasswell. Whether single-celled organisms or many membered groups, each similarly seeks to "maintain an internal equilibrium and to respond to changes in the environment in a way that maintains this equilibrium" (Lasswell, 1948: p. 38). Avoiding dysfunction and systemic breakdown requires a consensus in the attention and views of leaders, experts, and various publics (Lasswell, 1948: p. 51). In some studies, the dysfunctions of the current professionalized system such as not enabling the correlation of different social groups (see Yankelovich, 1991) compare negatively to citizen journalism, which in the best cases is seen to create a working if not harmonious fit between agendas of the institution, organization, profession, and publics. Through a functionalist approach, professional journalism and citizen journalism are often compared regarding their ability to bringing about such a consensus.

Functionalist studies of citizen journalism assess it in national or international spheres. To investigate to what degree the introduction of citizen journalism upsets the economic equilibrium of profitability in various local US media markets, Lacy et al. (2011) found that while public-affairs blogs complement radio and TV (and thus pose no economic threat to their viability), they substitute for alternative newsweeklies by causing the readerships and resulting advertising revenue of the latter to drop. Xin (2010) found in China that citizen journalism had been generally incorporated into the workings of professional journalism, and its potential systemic disruption thus contained. However, the study also noted that citizen journalism outside professional journalism also existed, largely to promote various forms of nationalism. In their comparison of eight European countries and the USA, Domingo et al. (2008) found that citizen journalism had also been incorporated by professional journalism with minimal disruption, largely by restricting citizen participation to opinions and feedback, not extending it to news reporting as well.

Technological Determinism and Convergence

The relevance of technological change to citizen journalism is the focus of studies of convergence. Disruptions are attributed largely to the Internet, which provides the potential of open access and worldwide distribution. Studies of citizen journalism in this perspective become part of broader attention to changes throughout the full range of creative industries, thus coinciding with other fields of study such as sociological studies of labor, work, and workplace organization (Hesmondhalgh, 2002; Banks, 2007; Deuze, 2007).

This perspective takes a functionalist interest in systemic analysis, but extends it geographically from discrete localities to a globalized process (Castells, 1996). Indeed, in his discussion of what he calls 'network journalism,' Heinrich (2011) notes as much in his assertion that the emergence of citizen journalism is just one instance of a transformation in media work "driven by two processes: globalization and technological advances in the form of digitization" (p. 2). Studies of convergence pose questions about systemic disruptions or equilibrium, with the evaluative yardstick being that of normative press theory. While scholars such as Jenkins (2006) regard convergence as the steady democratization of cultural production, others such as Cammaerts (2003) argue that user production – which includes citizen journalism – pacifies audiences with a false sense of agency which links participation to consumption instead of to critical reflection.

Whether referring to the consolidation of jobs, roles, content, or companies that earlier had been discrete, convergence as an organizing concept sets aside questions concerning which side – professional journalism or citizen journalism – is carrying the day. Instead it focuses on emerging hybrids of professional–citizen organizations and practices. For example, some studies claim that citizen journalism has been fully absorbed by professional journalism, such as the case of the Community Connection initiative of New Jersey Online studied by Boczkowski (2004). Similarly, Compton and Benedetti (2010) find that professional journalism will maintain its integrity in the face of citizen journalism.

However, conclusions by other scholars emphasize emergent hybridities of production and consumption. Uricchio (2004) refers to the emergence of 'collaborative networks' as the organizational manifestation of convergence driven by technological change, and Bruns (2008) addresses the hybridization of roles through the concept of 'produsage' (an amalgam of 'production' and 'usage'). Deuze et al. (2007) conduct a multinational comparative study and find the emergence of new professional–citizen hybrids. Jouët (2009) finds a similar case of hybrid journalism in France.

Social Constructivism

Social constructivism departs from the prior perspectives in a number of ways. As inferred by the term 'constructivism,' it seeks to account for beliefs, roles, organizations, and systems as ongoing processes rather than established and stable things. Accordingly, studies of citizen journalism with this emphasis seek not to define or measure citizen journalism so much as to account for the processes that bring it into being and that maintain it.

A number of sources inform such work. In their emphasis on building workable public deliberation, studies of civic and public journalism (an earlier cousin of citizen journalism) made their cases via philosophical pragmatism (Coleman, 1997;

Bybee, 1999; Rosen, 1996; Merritt, 1998; Eksterowicz and Roberts, 2000). The relevance of pragmatism for newswork and communication can be traced most overtly in the USA by reference to the work of social philosopher John Dewey (1927; Carey, 1989; Rosenberry and St. John III, 2010; Steiner and Roberts, 2011). However, more recent social-constructivist studies of citizen journalism rely more fully on the constructivism and phenomenology of Berger and Luckmann (1967), which came into relevance in studies of the sociology of newswork by Tuchman (1978) and others (a good overview is Carey, 1989).

Social-constructivist studies of citizen journalism seek to determine whether and to what degree workplace norms and self-understandings of news not only differ between citizen journalism and professional journalism, but also how these understandings either support or dissuade the integration of one into the other (Tilly and Cokley, 2008). Studies rely upon mixes of analysis of news stories (as indications of the norms and beliefs used to report and write them, as well as of the situational resources and restrictions of time, money, access and so on) and analysis of direct interviews, with the presumption that the views expressed indicate relevant norms and practices at work.

One group of studies finds little in common between the two kinds of journalism. Carpenter (2008) finds that citizen journalists and professional journalists use different routines while reporting and writing. While professional journalists relied more on official sources, citizen journalists used opinion and unofficial sources, with the implication that citizen journalists' reports adhere less so to professional norms. In a study based on interviews with citizen journalists and professional journalists about how they went about reporting and writing their stories, Reich (2008) comes to similar conclusions. Citizen journalism differs from professional journalism due to different situations and resources available to each, thus reflecting badly on citizen journalists in relation to professional norms. Other studies investigate more thoroughly professional journalists' perceptions of political–economic pressures that structure their work (Vujnovic et al., 2010).

However, other studies conclude that there exists a good deal of commonality between citizen journalists and professional journalists. Robinson and Deshano (2011a) find that both groups share the liberal–pluralist professional ideology. Williams et al. (2011) find that the BBC accommodated citizen journalism within existing professional routines, thus posing little challenge to professional standards. Lewis et al. (2010) find differing opinions and practices among a sample of community newspaper editors. While some editors oppose citizen journalism in any form other than reader feedback and opinion in order to uphold professionalism (also the conclusion of Singer and Ashman, 2009), other editors approve it due to encouraging closer involvement of public and the newspaper as well as helping provide additional labor at little extra cost. Pantti and Bakker (2009) link the relevance of professional norms to medium. They argue that user pictures are deemed to be more credible and less reliant on skill and judgment than user reporting, and are thus integrated more easily by the profession.

Still others conclude that, far from having little or no impact on professional journalism, citizen journalism is having a dramatic impact. Thurman (2008) concludes that much of the debate among editors and journalists about citizen journalism is spurred by increasing pressures of profitability and their pressures on newsroom routines (see also Hermida and Thurman, 2008). Paulussen and Ugille (2008) find a similarly determinant role of newsroom structures, work routines, and professional beliefs. These, and not intentional resistance to citizen journalism by professional journalists, explain the resulting resistance to its adoption.

Critical Discourse Analysis

Critical discourse analysis introduces a different problem altogether. It posits inequalities as intentional and structurally necessary (not aberrations, distortions, or dysfunctions), which remain opaque to other perspectives (Williams, 1975). By conceiving discourse as a social activity (not as a noun labeling a collection of words or meanings), such studies also share a constructivist predilection with process instead of a positivist preoccupation with attributes and characteristics of fully formed elements. Finally, such studies tend to define citizen journalism and professional journalism relationally instead of as opposites or as mutually exclusive. As such, its assessment of citizen journalism is often posed in terms of struggle and uneven merger instead of the comparative strength of opposing positions or fully realized hybrids.

The extent to which the presumptions of other perspectives are left behind can be seen in a variety of work. Robinson (2009) describes very complex relationships between citizen journalism and professional journalism in a study of news stories written and published after the 2005 Hurricane Katrina disaster in the USA that flooded the city of New Orleans and others on the coast of the Gulf of Mexico. Instead of opposing citizen journalism to professional journalism, the study identifies a complex array of different characters, themes, perspectives, overall messages, and claims of authority by news items written to mark the one-year anniversary of the Katrina disaster. Such findings suggest the inadequacy of claims about which side (professional or citizen) has the upper hand or claims of a synthesis of the two. Contrary to such claims, Robinson suggests the existence of "a patchwork of journalism and citizen work that represents the acting out of the tensions from these role shifts" (p. 810).

Moyo (2011) frames the use of blogging by nonprofessionals within the 2008 election in Zimbabwe within changes not only in technology, but also within changes in the very nature of journalism increasingly characterized by "increased participation, multimodality and multidirectional flows" (p. 756). The emphasis on 'multi' rather than binary (either citizen or professional) broadens consideration of the complexity and interrelatedness of citizen journalism with many other spheres and practices. Citizen journalism is not a clear opposite, nor clearly different from professional journalism, but a provisional activity generated through complex relationships as well as the particular context in which it takes place. While Moyo sees on one hand the emergence of "a hermeneutic, constructivist, and postmodern approach to journalism" very different from the professional mode, this citizen journalism still shares with the professional mode "the idealism of the neoliberal discourse that empowers [both of] them as the watchdog of the state, but this simultaneously

deprives them of the capacity to conceptualize the alternative in truly radical ways" (p. 758).

By contrast to organizations and efforts institutionally outside professional journalism organizations, Kperogi (2011) assesses citizen journalism as enabled by CNN News and its iReport feature. The study traces the "enthusiastic valorization of citizen media" to "the idea that they exist apart from and, in fact, in opposition to, the mainstream [professional] media" (p. 315). By contrast, this study suggests a much more nuanced assessment. On one hand, citizen-submitted items are successfully incorporated not through intentional editorial decision, but discursively, by "construct[ing] the 'normality' of prevailing conventions of news judgment," which people who submit items accept, if only provisionally (p. 320). On the other hand, and despite this largely successful management, other iReport items "openly criticize CNN's coverage of certain news events" and that "give radical perspectives on the US economic recession," suggesting the permeability of means of control (p. 322). Citing theorists such as Gramsci and Zizek, Kperogi (2011) emphasizes the ongoing processual nature of this situation by noting that "there is always contestation and that the volitional consent of the broad segment of subordinate classes has to be perpetually won and re-won" (p. 326).

What thus becomes important is not to assert which side has won, but what the terms of the struggle between the sides is and, furthermore, how this struggle constitutes the very sides in contention.

Historical Studies

Finally, historical studies share many aspects with critical discursive studies. They ask similar questions about the ongoing, processual constitution of citizen journalism (instead of about its imputed and ostensibly fixed and intrinsic nature). However, their distinctive contribution is in expanding the time frame and range of interrelationships that enable this constitution.

A number of historical studies of citizen journalism emphasize its historicity instead of universality by noting its deep relationship with the industrialized West. In doing so, the imputed universal effects of digital technologies is recognized as determined more deeply by social intentions within particular social conditions (Williams, 1975). To underscore this point, Pidduck (2010) argues in favor of "conjunctural studies that trace how social and political agents deploy different media within particular historical, cultural, and political frameworks" (p. 475). It addresses the limits of citizen journalism within the context of the autocratic regime of Burma, "notorious for extensive censorship and for the harassment and imprisonment of journalists" of whatever kind (p. 475). Compared with the view that "that the decentralized, participatory architecture of 'new media' is intrinsically democratic," Pidduck argues that contextual awareness (such as of low internet penetration in Burma) moderates such claims when extended globally.

Hamdy (2009) addresses the effectiveness of citizen journalism as operating outside professional journalism in Egypt prior to the changes wrought by the Arab Spring. The study emphasizes presciently the multitudinous challenges posed by Arab bloggers to the authority of the state, the laws and regulations active at the time to try to limit these challenges, as well as citizen journalists' tactics to avoid such limitations. Bosch (2010) discusses the South African experience, and concludes in that comparatively industrialized country that all can be seen as part of an 'online public sphere,' which is an allusion to Habermas's influential formulation (Habermas, 1989; Calhoun, 1992). Finally, Hamilton (2008) seeks a broader historicization of citizen journalism by locating its dynamic and emergence within the centuries-long formation of capitalist media organization and its steady challenge brought on by accelerating pressures of competition in the contexts of the emergence of modernism and technological change.

Conclusion

Despite the immense variety of perspectives, most studies of citizen journalism are structured by a framework of inquiry defined by normative liberal–pluralist press theory and the assumption of a categorical distinction between professionals and nonprofessionals. That constructivist, critical, and historical perspectives for addressing citizen journalism turn such a framework itself into a problem deserving of theoretical attention continues to move studies of citizen journalism into new and exciting directions.

Abstract

Since the mid-2000s, there have been significant shifts in geographic information production and dissemination, marked by the emergence of user-generated geographic information. This form of mapping and spatial data production, facilitated by an array of Web 2.0 technologies and location-aware mobile devices, has allowed ordinary citizens to carry out mapping practices without formal training in Geographic Information Systems or cartography. This article aims to provide an overview of the research on these mapping practices, known as citizen mapping; the focus is on three broad strands of work: spatial data in citizen mapping, citizen mapping as social process, and related methodological challenges and developments.

Introduction

Traditionally, map and spatial data production has been mainly carried out by government agencies and professionals given the technological complexities and associated high costs. Since the mid-2000s, however, the rise of Web 2.0 technologies (such as blogs, wikis, and social networking sites), combined with the increasing availability of mobile devices with global positioning systems (GPSs) and high-resolution remotely sensed imagery, has enabled an unprecedented number of individuals and social groups to generate and share maps and spatial data online (Elwood, 2009). In particular, citizens increasingly play an active role in producing and sharing spatial data at an unprecedented scale (Haklay et al., 2008). Citizen mapping refers to the mapping practices that are carried out by lay persons, enabled by these technological transformations. While forms of such mapping practices are highly diverse, they are characterized by user-generated geographic information production such as contributing to mapping databases through online mapping platforms and generating map mashups that combine multiple sources of spatial and nonspatial data on one shared online interface. A growing range of practices have been undertaken through citizen mapping, such as monitoring environmental change, mapping crises, responding to emergencies, addressing neighborhood change and needs, and mobilizing activist efforts (Elwood, 2009; Miller, 2006; Crutcher and Zook, 2009).

This notion of citizen mapping is highly related to other notions emerged to address this explosive growth of user-generated geographic information such as 'volunteered geographic information' (VGI) (Goodchild, 2007), 'the geoweb' (Scharl and Tochtermann, 2007), 'maps 2.0' (Crampton, 2009), and 'neogeography' (Turner, 2006). All emphasize nonexperts producing and sharing geographic information, facilitated by various online mapping platforms such as OpenStreetMap, Wikimapia, Google Maps, etc. As such, the line between traditional map makers and map readers is increasingly blurred (Budhathoki et al., 2008). This phenomenon can also be seen as part of the broader context of the 'exaflood of big data' (Sui et al., 2012), which has brought profound influences on how geographic information and data are produced and shared (ibid). The following sections will take up major debates around the emergence of citizen mapping and related practices.

Conceptual Debates

A rapidly growing body of work investigates the emergence and impacts of citizen mapping via three major, closely related, themes: (1) the forms and characteristics of the data created through citizen mapping; (2) the social and political implications of these mapping practices; and (3) the methodological challenges of working with and researching these new forms of geographic information and practices.

Spatial Data and Representation in Citizen Mapping

Early discussions focused on the digital data generated through citizen mapping in relation to conventional ways of spatial data production and dissemination, including how data are created and shared and for what purposes as well as data content and characteristics (Elwood, 2009). These discussions have been strongly informed by research in spatial data infrastructure (SDI) and data handling in geographic information science (GIS) and related fields. Research has recognized the significant shifts brought by citizen mapping practices on the scale and scope of geographic information production and the implications for data management, representation, and credibility.

Studies have noted that these technological transformations have led not only to unprecedented volumes of geographic information production and dissemination online by an increasing range of mappers, but also to changes in what is being mapped (e.g., Haklay et al., 2008; Elwood, 2009). These highly open and interactive mapping platforms allow for a much more diverse group of participants, which in turn results in a much wider range of topics in these mapping practices and representations. In particular, citizens can incorporate more localized and everyday information into the mapping platforms such as through mapping mashups. As such, citizen mapping practices generate tremendously vast and heterogeneous data (Elwood, 2009). One of the characteristics in these everyday mapping practices is the tendency to rely more on everyday language, which suggests a more 'platial' context than traditional GIS (Elwood et al., 2012: p. 363). For example, place names and points of interests play a significant role in citizen mapping (ibid). In contrast, traditional GIS tends to focus on planimetric features of mapping and conducting

topological overlay for calculation, visualization, and modeling of spatial data (e.g., Foresman, 1998).

Related to these characteristics of citizen mapping data are questions about how existing SDIs, which usually follow a top-down model, can deal with the distributed and user-generated data derived from citizen mapping (cf Elwood et al., 2012). Researchers have suggested incorporating citizen mapping data as part of a 'patchwork' approach to contribute to existing SDIs (Goodchild, 2007). For example, an initiative of citizen-based measurement of small particles in the air through daily activities in Milan, Italy, shows that the levels of these small particles collected by citizens are 20 times higher than those collected by the monitoring stations (Craglia, 2007). This approach, along with other efforts to develop systems to handle and integrate Web-based geographic information, is informed by research on the long-standing issue of interoperability in GIS (e.g., Craglia, 2007). The idea of building SDIs from the bottom up via grassroots and community organizations has also received attention (e.g., Elwood, 2008). Moreover, issues of the digital divide are important to the development and usage of SDIs and user-generated spatial data, defying a one-size-fits-all approach or a linear conceptualization of data/infrastructure availability and usage (e.g., Sui et al., 2012).

Issues of data quality and credibility have drawn notable attention (Elwood et al., 2012). The quality of citizen mapping practices may vary significantly, while some believe that many of these practices can potentially reach a high level of accuracy ensured by collective intelligence. For example, Haklay (2010) compares citizen mapping data produced through OpenStreetMap with the data produced by Ordnance Survey, the national mapping agency in the United Kingdom. His study shows that the OpenStreetMap data on London and England are quite accurate in this comparison. Yet, despite some successes, producing high quality data through citizen mapping remains a significant challenge (Elwood et al., 2012). At the same time, research has called for approaches that reconceptualize notions of information validity and credibility regarding user-generated geographic information (Flanagin and Metzger, 2008; Poore and Wolf, 2012). For example, Flanagin and Metzger (2008) note that credibility can be viewed as an objective property or a subjective perception, with the former emphasizing accuracy and the latter believability. They suggest that viewing credibility as a perceptual variable helps to address the core issues of publicly VGI that tend to be "more about which information, opinion, or perspective people believe" (p. 141), which is useful for those who use such data for social and political purposes. Meanwhile, credibility as accuracy can be applied to these mapping practices when the results and knowledge produced in such practices can be evaluated through widely shared standards that are less dependent on local contexts. For example, the credibility of locations annotated by WikiMapia users can be assessed using established standards of locational accuracy. Poore and Wolf (2012) use the notion of 'metadata squared' to illustrate the bottom-up approach facilitated by the Web 2.0 technologies, which results in more flexible and accessible metadata generation including a proliferation of ancillary data that describe the map and include discussions and debates around the map.

It is clear that the distributed practices of citizen mapping have called into question "conceptions of authority as centralized, impenetrable, and singularly accurate", which may lead to "a shift from a model of single authority based on information scarcity and hierarchy to a model of multiple distributed authorities based on information abundance and networks of individuals" (Flanagin and Metzger, 2008: p. 143). Simultaneous with efforts to incorporate existing ways of evaluating the credibility of user-generated geographic information is the recognition that data characterized by experiential and quotidian representations gain credibility through practices of transparency and peer-to-peer review such as peer verification and witnessing (Elwood and Leszczynski, 2013). These forms of representing experiential and situated knowledge through citizen mapping have drawn significant attention from scholars, for which these mapping practices are examined as social processes.

Citizen Mapping as Social Processes

A burgeoning body of work investigates citizen mapping as social processes and their social and political implications (cf Elwood et al., 2012). This research strand has been greatly informed by research in critical GIS and critical cartography (Crampton, 2009; Elwood, 2011; Pickles, 2004). Critical GIS and critical cartography investigate the ways in which spatial data and knowledge are generated, represented, and shared by various institutions, organizations, and individuals in different contexts (e.g., Sheppard, 2005). Critical GIS research was stimulated by early critiques of GIS in the early 1990s, in which a number of human geographers called for attention to the social impacts of GIS regarding asymmetries of power and knowledge production, privilege and marginalization, state surveillance, population control, marketing, military operations, and so on (cf Pickles, 1995). Later responses argue that GIS is not inherently positivist (Schuurman, 2002). Subsequent work has broadened access to GIS technologies and data for socially marginalized groups and grassroots community organizations, resulting in rich accounts and discussions of participatory mapping and public participation GIS (PPGIS) (Sieber, 2006).

Together, these studies have provided important insights into understanding how citizen mapping practices may change spatial data production and associated knowledge construction (Elwood et al., 2012; Crampton, 2009). This work has led to discussing the potential of empowerment and facilitating public participation through citizen mapping. Some studies suggest that the greater user friendliness and reduced spatial and temporal constraints of citizen mapping can facilitate greater civic engagement and participation in a number of contexts (e.g., Miller, 2006). Strongly influenced by the PPGIS literature that seeks to tackle issues of uneven GIS technologies usage and spatial knowledge production (cf Sieber, 2006), researchers have examined how these mapping practices might empower citizens and citizen organizations. For example, in the aftermath of Hurricane Katrina in New Orleans, USA, in 2005, citizens used the platform of Google Maps to post information about rescue needs, creating what Miller calls "a map of the disaster" by local people or those who were able to provide local information in this situation

(Miller, 2006: p. 195). Recent years have seen growing efforts to engage with crisis mapping, drawing participants across the world in cases such as responses to the Haiti Earthquake in 2010 where governmental responses and services might be lacking. However, effects of such activism are mixed and varied (Elwood, 2011), with possible unintentional outcomes such as facilitating a form of voyeurism (Parks, 2009).

Continuous efforts have been made to further investigate the sociopolitical implications of these mapping practices and what forms of politics might be emerging or reconfigured in these processes. For example, through investigating five online initiatives that engage with the geoweb for activism and civic engagement, Elwood and Leszczynski (2013) suggest that these new practices entail constructions of visual experiences that are highly individualized, interactive, and exploratory. Through constructing such experiences aiming to affect social and political change, these organizations leverage these mapping platforms to gain legitimacy of knowledge claims, which in turn constitute new forms of knowledge politics.

A related aspect in the area of civic engagement draws upon notions of citizen science and open source software movements. The 'patchwork' approach regarding SDI developments with contributions from citizen mapping noted earlier can be considered in this light. A prime example is the development of OpenStreetMap. This is a free and open source online mapping platform which aims to provide a digital map of the world, a somewhat Wikipedia version of mapping (**Figure 1**; Haklay et al., 2008; Poore and Wolf, 2012). Registered users may upload their own GPS tracks and use out-of-copyright maps and Bing aerial imagery for references to create maps on OpenStreetMap (Haklay, 2010). At the time of writing, there are more than 1 million registered OpenStreetMap users and over 3 billion GPS points uploaded (http://www.openstreetmap.org/stats/data_stats.html). It is expected that these numbers will continue to grow. In general, it is considered that these mapping practices do not require formal training in traditional GIS or cartography. Explanations and discussions of associated steps and procedures are available through respective wiki pages, forums, and email lists. Such discussions help to foster community building to engage with mappers (Poore and Wolf, 2012).

Related to the issue of empowerment and civic engagement are motivations, identities and subjectivities, which shape and are shaped by these mapping practices (Budhathoki et al., 2008; Dodge and Kitchin, 2007; Elwood, 2011). A key issue has been reconceptualizing the notion of 'the user' (e.g., Budhathoki et al., 2008). Attention has also been given to the intersection of subjectivities and highly individualized and interactive electronic communication technologies (e.g., Kingsbury and Jones, 2009). In these discussions, the mapping subject is a hybrid one with constant self-identity construction, in contrast to the traditional view of a rational and coherent mapping subject. These dynamic and fragmented subjectivities, however, can be actively employed to represent alternative and complementary forms of resistance and activism (Cobarrubias and Pickles, 2009).

Meanwhile, researchers have called for more studies investigating how these spatial data and mapping practices may perpetuate existing inequalities, produce new forms of exclusion and surveillance, and raise concerns about privacy encroachment (e.g., Crutcher and Zook, 2009; Elwood and Leszczynski, 2011). Crutcher and Zook (2009), for example, show how racial relations affect the way people use these online mapping services. Elwood and Leszczynski (2011) analyze how the notion of privacy is negotiated and contested in the practices of user-generated geographic information production and dissemination including geotagged images in the age of Web 2.0. Moreover, Leszczynski (2012) examines citizen mapping practices through the lens of political economy. She argues that the significant shift to more user-generated forms of spatial data production indicates new regimes implicated in neoliberal political economy reflected in three dimensions: free labor, private ownership, and unaccountability. In these new regimes, the state is moving toward a role of "one of many producers and facilitator or institutional body of oversight" (Leszczynski, 2012: p. 78). Nonstate agencies, at the same time, are playing a more active role in geographic information provision, dissemination, and utilization.

Citizen mapping can also be situated in the context of pervasive computing (e.g., Dodge and Kitchin, 2007). For example, Dodge and Kitchin (2007) examine the emergence of life-logs as a form of such pervasive computing and their impacts. They note that while these technological transformations have the potential to provide rich autobiographical narratives for individual empowerment and enrichment, they also raise broader social and political questions such as concerns of access to such data by third parties which may result in data abuse and unethical usage.

Methodologies for Researching Citizen Mapping

As discussed earlier, citizen mapping practices have produced tremendous volumes of highly heterogeneous data, which brings new methodological challenges to researchers both in terms of working with these vast and diverse data and investigating these new forms of geographic information. Elwood (2011) provides an insightful overview of methods in research of the geoweb, a term used to describe the vast spatially referenced information produced and shared online, which is highly relevant to citizen mapping practices. Elwood (2011) suggests two important trajectories: one focusing on research *with* geoweb-based information and the other more on research *about* the geoweb. Specifically, regarding research with geoweb-based information, scientific information visualization approaches have been explored to investigate broader patterns in these complex and large datasets (e.g., Jiang, 2012). For example, Jiang (2012) uses geospatial analysis approaches to investigate and visualize mobility patterns detected from user-generated geographic information. In particular, he presents three examples of employing computational geography using OpenStreetMap data, contributed by numerous citizen mappers, for such analyses underpinned by the concepts of topology and scaling. Topology is defined as the study of spatial relationships that remain invariant despite geometric distortions. Scaling refers to the power-law distribution of geographic spaces where there are more small things than large ones, for example, in the case of cities. In one of the examples, the whole Swedish street network database was extracted from

Figure 1 Screenshot of OpenStreetMap. © OpenStreetMap contributors.

OpenStreetMap and used to show hierarchical levels of the street network. Such analyses can have important implications for understanding traffic flow (Jiang, 2012).

Critical visual methods have been employed to examine the everyday mapping practices of the geoweb (e.g., Graham and Zook, 2013). This strand of research emphasizes an epistemological hybridity of visualization (Elwood, 2011). Such an approach may involve visualizing the dynamics of citizen mapping practices as well as understanding these mapping practices as visual practices through engaging with other qualitative methods. For example, Graham and Zook (2013) employ a method of mapping geocoded content on Google Maps to examine the geographies of digital annotations and how these patterns intertwine with constructions of place. Through visualization, they show that the density of digital geocoded content is highly uneven, in which Western Europe and North America have the highest amounts of geographically annotated content per capita, and much of the rest of the world has a small amount of augmented information. While these uneven patterns largely mirror past patterns of the Web in the 1990s, new geographies are also emerging such as the relatively higher densities of some non-Western countries compared to their status in the 1990s. At another level the authors further investigate the spatial footprints of different languages in the geoweb in five particular regions (Canada, Spain, Belgium, France, and Israel and the Palestinian Territories) through visualizing aggregations of certain keywords. The results provide a vivid illustration of the "geolinguistic contours of a place and its representations in the geoweb" (p. 95). Other methods such as discourse analysis, participant observations, interviews, and surveys have also played a role in understanding citizen mapping as visual practices and their associated implications (e.g., Kingsbury and Jones, 2009; Elwood and Leszczynski, 2013).

Summary

In summary, a burgeoning body of work in GIS and geography seeks to grapple with a range of issues and questions derived from the emergence of citizen mapping and other user-generated geographic information production. This body of work has outlined a number of technological, socioeconomic, and subjectivities transformations underpinning the emergence of citizen mapping (e.g., Goodchild, 2007; Sui, 2008; Haklay et al., 2008; Elwood, 2011). In particular, research has sought to analyze the content and characteristics of these data produced in these processes. Studies have also attempted to investigate citizen mapping as social processes and the socio-political implications of such processes. These inquiries are carried out through several broad perspectives including SDI construction, empowerment and disempowerment of different social groups and individuals, and meanings of everyday practices (e.g., Elwood, 2011; Kingsbury and Jones, 2009). These mapping practices and the data they generate present new challenges for researchers with respect to both researching with such data and researching on these data and associated processes. Among many approaches, geovisualizaiton and critical visual approaches have been utilized to understand and interpret these mapping practices. It is important to note that citizen mapping continues to evolve and the volume of data continues to grow on a daily basis. Many key questions remain to be answered including how to better understand ways of incorporating, interpreting, and engaging with these mapping practices in an increasingly shrinking, but also highly divided world in view of rapidly evolving communication and spatial technologies (Sui et al., 2012).

Citizen Participation

Howell S Baum, University of Maryland, College Park, MD, USA

Abstract

Participation in making public decisions that affect individual and collective interests is a basic element of democratic citizenship. Citizen participation can make decisions more knowledgeable and legitimate. Besides possible substantive benefits, participants can gain from acquiring skills, knowledge, social capital, and power. Challenges in designing decision processes to provide such benefits include enabling all participants to exercise similar power, including participants representing a wide range of interests and perspectives, accommodating low-income citizens' difficulties participating, and using electronic media to enhance participation and knowledge.

Citizen participation refers to involvement of members of the public in societal governance. In planning, organizing, community development, and related fields, the term includes activities that enable significant numbers of individuals and representatives of groups to influence public (and sometimes private) decisions that affect their interests. Historically, 'citizen participation' emerged from efforts to empower racial minorities and economically disadvantaged groups to take part in government decision making.

Citizen Participation as Citizenship

The growth of industry and the arrival of millions of immigrants to work in manufacturing plants swelled American cities in the late nineteenth century and began to make America an urban nation. Not only the great population growth, but also the physical, social, and cultural changes in cities wrought by new residents from southern and eastern Europe presented challenges regarding how cities would be governed. In response, members of local economic and professional elites spearheaded wide-ranging progressive reforms in cities' physical infrastructure, social welfare institutions, and governance. They created commissions, including planning commissions, and other institutions in an effort to ensure that the wealthy and well educated, rather than the political bosses tied to the immigrant workers, would dominate the local government.

Decades later, when the Johnson Administration launched the 1960s War on Poverty, federal policy makers introduced expectations of 'citizen participation' that would involve the poor and racial minorities in making decisions about urban reforms. An important stimulus for this new orientation was the civil rights movement, which epitomized and pushed for grassroots participation in public institutions and policy making. The designers of the Community Action Program believed that local citizen involvement in the War on Poverty would bring benefits both by introducing new ideas and by bypassing local officials who resisted change. Many local elites resisted new participants, but federal language unambiguously called for expanded public involvement. The Economic Opportunity Act of 1964, the hallmark of the War on Poverty, declared that "The term community action program means a program … which is developed, conducted, and administered with the maximum feasible participation of residents of the areas and members of the groups served." (The Economic Opportunity Act of 1964, P. L. 88-452, August 20, 1964, Sections 202 (a) and (c)) In 1966, the Model Cities Program began with a call for 'widespread citizen participation'. The same year, a US Department of Housing and Urban Development program guide listed 'ethnic or racial groups' among desired participants in local urban renewal citizen advisory committees. The War on Poverty aimed to activate the urban poor, particularly blacks (Marris and Rein, 1982; Moynihan, 1970).

American society had changed conspicuously over the preceding century. The slaves had been freed. The continent was filled out with states and localities. Millions of European immigrants had brought foreign cultures to American cities. The franchise had been extended to all white men, blacks, and women. Government had become a huge, multidepartmental, multilevel bureaucratic welfare state. Two hundred million Americans had interests in governmental actions, and there were no ready channels for them to be heard, much less to have influence. The new citizen participation would be an experiment.

Local government officials, agency professional staffs, and elites typically looked less favorably upon this experiment than did federal policy makers and the intended new participants, and the parties disagreed about the purpose of the experiment. At most, those who had traditionally made decisions commonly believed, 'citizen participation' would mean involvement that did not disturb existing power relations. In contrast, low-income and black residents expected 'citizen participation' to give them power over policies and programs. The War on Poverty coincided with activism to register blacks to vote and gain what they regarded as 'first-class citizenship.' Consistently, racial minorities and the poor understood 'citizen participation' to be central to, and an extension of, citizenship.

People spoke of 'citizen participation' and 'community participation' interchangeably. On the one hand, since individual citizens belong to communities, by implication, communities are involved when citizens participate in decisions. On the other hand, 'community participation' can be more complex and demanding, insofar as it represents an expectation that a community as a whole influence decisions on behalf of collective interests. This broader meaning requires defining communities, identifying their interests, and elaborating ways communities can act in service of their interests. Thus, talk of 'community participation' expanded the meanings and expectations of 'citizen participation.'

A conventional concept of community, compatible with planners' view of the city as a physical place, defines the residents of a geographic territory as a community. In this view, often accompanied by the assumption that community members are homogeneous, participation of citizens is synonymous with community participation. In practice, however, residents of a place are likely to regard themselves as sharing interests only insofar as they have social relations, follow some common cultural norms, and identify with one another. Thus, residents of a place may or may not see themselves as a community and act as one. Moreover, the growth of nonspatial communities based on shared identities or interests has expanded the domain of 'communities' and added complexities to identifying community interests and promoting community action. Not only is citizen participation that involves communities more difficult to carry out than participation of individuals, but community participation also poses hard questions of defining community interests and determining when participants represent them.

Local government officials and their professional staffs have come to regard some kind of citizen participation as a normal part of decision making. They may speak of 'community participation' as well as of 'citizen participation,' although they may not attach a specific meaning to 'community.' Insofar as they distinguish 'community' participation from general participation of a jurisdiction's residents, they are likely to refer to a geographic neighborhood or subdivision. For their part, residents or community members are more likely to think in terms of community identities and interests than those of a whole jurisdiction, and they may organize to direct officials and staffs to look at the specific people or areas that matter to them.

Normative and Practical Arguments for Citizen Participation

Whether government officials and professionals who work with the public support active, not just formal, participation, and whether citizens invest much time and effort in participating depends on what they consider the rationale for and benefits of citizen participation.

The primary normative argument for citizen participation is that, as an exercise in citizenship, it is required by democracy. In this view, people have the right to deliberate on and influence decisions affecting their interests. This right does not depend on whether citizens are experts or especially knowledgeable on issues.

In fact, however, a practical argument for citizen participation emphasizes ways in which a participatory process contributes useful knowledge to decision making. When people feel that current conditions need changing, they may be unsure what exactly the problem is, what values they should use in deciding what to do, what alternatives would benefit them, and which is the best course to take. Experts may have specialized or abstract knowledge on the substance of issues under consideration, but ordinary citizens have knowledge about local conditions. For example, a housing expert may know about markets, policies, and programs in general, but residents may know about the history of housing, the housing market, cultural values related to housing, and influences on homeownership in their particular neighborhood. Both kinds of knowledge together are useful for analyzing housing conditions, framing problems, formulating alternatives, and developing strategies for change. In addition, regardless of who knows what, a process in which public officials, professionals, and ordinary citizens discuss issues together will raise questions, identify problems, and generate new ideas and knowledge that would not have been available in the absence of citizen participation.

A second practical argument for citizen participation is that people who take part in formulating problems, generating ideas, identifying goals, and developing proposals feel invested in the results. They regard plans as legitimate and authorize action to implement them. For example, when residents have an active, influential role in planning to improve public transit, they are more likely to support the final proposals than if they were not consulted or if they only observed deliberations by public officials and agency staff. Experience shows that, even if officials or experts come up with the same plans that residents favor, citizens are less likely to endorse the ideas if they are not involved. Thus, citizen participation serves the practical interests of elected officials and professionals in securing legitimacy for decisions.

A third practical argument for citizen participation is contained within the first two: citizen participation can help resolve conflicts over problems and solutions. A deliberative process including citizens offers an opportunity for people with different positions and interests to reason together. They can compare assumptions and information and can do research to see whether one position is more realistic than another or whether there is another alternative altogether that is preferable to any of the contesting positions. Insofar as participants learn together, they may come to feel that their shared knowledge is authoritative. Moreover, simply the process of discussing ideas and values may enable people who started off in conflict to develop more sympathetic views of one another and form relationships that contribute to agreement. There is no sure method to resolve conflicts, but in these ways well-organized citizen participation contributes to broadly supported, knowledgeable decisions that are likely realistically to benefit many participants' interests (Briggs, 2008; Forester, 1989).

These practical arguments emphasize the tangible benefits of citizen participation: for example, more low-income households can afford decent housing, more inner-city residents can ride public transit to employment, shopping, and social services, and more neighborhoods can have nearby recreational facilities. In addition, the process of participation itself can benefit citizens, communities and organizations to which they belong, and the jurisdictions and larger society of which they are a part.

Individuals benefit from participation in several ways. First, they experience being a citizen, being a significant part of the political system. The activity may bring self-esteem and a sense of potency. In addition, participation enables citizens to acquire knowledge about conditions and policies and to develop skills in collecting information, deliberating with others, resolving conflicts, reaching decisions, and perhaps such specific skills as analyzing or preparing budgets, assessing the historic value of homes, and determining if air or water is safe. Each episode of participation gives citizens problem-solving knowledge and skills that can be used in other cases.

Further, participation enables citizens to develop relations with government officials, agency professionals, community and institutional leaders, and others with whom they can work and from whom they can get benefits in the future. In all these ways, participation enables individual citizens to advance their interests.

The communities and organizations to which citizens belong, which may themselves be represented in a decision-making process, benefit in analogous ways. Individuals bring their experience from participation to their organizations and communities, thus adding to the latter's collective competence. In addition, the relationships individuals have developed become the bases for social capital available to organizations or communities, potentially increasing internal bonds and extending bridges to outside entities with useful resources. As a result, communities and organizations develop increased efficacy and influence over resources that serve collective interests and the interests of members. In turn, more vital and potent communities and organizations are likely to attract members who will work, perhaps contribute resources, and consider the entities legitimate (Baum, 1997; Quick and Feldman, 2011; Mandarano et al., 2011).

Finally, larger jurisdictions and society benefit from the active citizenship of participants in decision making. Individual citizens are more attached to the collectivity, are more likely to contribute their competence and leadership to civic activity, and bring and build relationships that can resolve conflicts and identify common interests. As a result, the society is likely to be more cohesive, and societal institutions are likely to identify and address problems knowledgeably and legitimately in ways that serve many interests.

Challenges in Making Citizen Participation Effective Citizenship

Whether, in fact, citizen participation brings these benefits depends on how it is organized and managed. Designers of participation processes face four challenges: to enable all participants to exercise similar power over decisions, to include participants representing a wide range of interests in conditions affected by decisions, to accommodate low-income citizens' difficulties in participating, and to use electronic media and technologies to enhance participation and knowledge.

Empowering Citizens

By its nature, citizen participation challenges decision-making processes dominated by political and economic elites. The history of citizen participation includes many instances of resistance by elected officials, business executives, and others to including ordinary citizens in deliberations. Arnstein (1969) formulated 'a ladder of citizen participation' to distinguish gradations in the power that citizens exercised in American antipoverty programs:

Nonparticipation

1. Manipulation: placing citizens on powerless advisory committees for the purpose of 'educating' them or gaining their support for others' positions.
2. Therapy: trying to change citizens' beliefs, attitudes, or values as a diversion from analyzing and changing social conditions.

Degrees of tokenism

3. Informing: giving information to citizens but not requesting or listening to their points of view.
4. Consultation: asking citizens' opinions but not making a commitment to act on them.
5. Placation: placing a few citizens on committees or boards that have limited influence over policies and practices.

Degrees of citizen power

6. Partnership: sharing decision-making power with citizens.
7. Delegated power: delegating some decision-making power to citizens.
8. Citizen control: citizens have considerable independent power over decisions.

Such a hierarchy poses the question of what determines how much power a group of citizens have in a particular situation. One factor, implicit in Arnstein's formulation, is whether traditional decision makers are willing to share power and, if so, how much and in what ways they are willing to do so. Here, it is useful to distinguish three levels of power. Manifest, and the usual focus of debate, is influence over specific, overt decisions regarding plans, programs, and policies. Beneath these decisions are others concerning which alternatives get onto the agenda. Thus, citizens may have considerable power in selecting from options on the table without having influence in determining the array of possibilities. Still one level lower are decisions, frequently tacit, about which social conditions are defined as issues or problems and even considered for the agenda. Citizens may have influence in choosing among recognized issues for an agenda but have little power to make certain troubling conditions into recognized problems that might be considered for the agenda. Political and economic elites have been most willing to share power at the top level and progressively less willing at each of the lower two levels.

A second factor affecting citizens' power is their ability to organize to gain influence in relation to formal and traditional decision makers on any of these levels. Citizen groups can use their numbers, knowledge, competence, and connections in forming alliances with some parties or persuading others to go along with their desires in getting problems identified as issues, putting issues on the agenda, or selecting particular solutions for problems.

In recent years, conflicts between organized citizens and formal decision makers, as well as difficulties resolving conflicts, have induced public and nonprofit organizations to employ facilitators with dispute-resolution expertise to design and manage decision-making processes. These processes involve efforts to include representatives of all affected interests, to establish decision rules that offer more or less equal power to all participants, to provide participants with relevant information, and to combine discussion, mediation, negotiation, and other activities that would contribute to collective learning and agreement. In the planning field, such activities may be called 'communicative planning.' Still, while participants' interests in reaching decisions, perhaps fueled by frustration with long impasses, lead them to authorize facilitators to design collaborative processes, more powerful participants

may resist sharing power with ordinary citizens. Hence, a challenge to citizens and those who want to empower them is to organize and negotiate for decision arrangements that involve relatively equal power for all (Forester, 2009; Innes and Booher, 2010).

Nevertheless, citizens who have had little experience making public decisions or negotiating with elected officials, corporate executives, or other powerful actors may be intimidated or may not know how to exercise influence. Under these conditions, a facilitator can help them act more effectively. Another handicap citizens may have is that they have less general knowledge or specific information about issues. This may be particularly so when the issues involve scientific or technical knowledge, such as questions of environmental quality. Industrial leaders may employ or routinely consult with experts, while lay citizens may find issues overwhelming, imagine that they could never understand them, and feel intimidated by others who speak fluently about them. Again, a facilitator can be instrumental in aiding not only laypersons, but everyone, by including experts in deliberations and structuring discussions so that participants can share and analyze information together and come to common understandings about how to assess conditions (Brody et al., 2003; Medoff and Sklar, 1994).

Representing Citizens and Communities

Time and space limitations make it impossible to include everyone affected by a public issue in making decisions. At the same time, not everyone with a stake in an issue wants to participate. Thus, any decision process includes only a sample of interested parties. If everyone has the same interests, then whoever takes part, whether a few or many, can represent these interests. However, unanimity of interests is rare; what makes a condition a public issue is the fact that people see it differently and want different actions to change or preserve it. Hence participation presents a question of representation: Does someone speak effectively for each group that has particular interests in the issue? The answer to this question depends on identifying the different interests and those who hold them. When an issue is relatively simple and the number of affected parties relatively small, it is easier to identify interests and people holding them. Many issues, however, are complex and affect multiple parties, and in these instances, representation poses challenges.

Early public commissions in planning and other fields were elite groups, composed of leaders in business, philanthropy, 'society,' the professions, cultural institutions, politics, religious institutions, and universities. These people claimed to have broad knowledge of local affairs and the ability to identify and speak for various citizens' interests. Advocates for 'citizen participation' in the 1960s challenged the representativeness of such bodies, calling attention to the typical exclusion of the poor and racial minorities. The social movements and poverty programs of that decade contended that the poor and racial minorities were normally the best exponents of their interests and hence should participate directly in making decisions. In the last decades of the twentieth century, government bodies, nonprofit organizations, and community organizations gave greater, more explicit attention to selecting and admitting participants who would represent broad interests.

There is no single correct way to define or measure representation and who or what is to be represented. One simple measure is statistical representativeness: whether participants resemble the overall population demographically, at least by race or ethnicity and by sex, perhaps also by age, income, and/or neighborhood. However, while statistical representativeness is politically prudent, as the sole measure of representation it has limitations. It erroneously assumes that everyone of the same race, sex, age, income, or neighborhood thinks the same and wants the same things. In addition, representation of demographic categories does not guarantee representation of interests. For example, on housing issues homeowners and renters have different interests, as may private developers and neighborhood associations. Similarly, in decisions about community development, merchants, social service providers, religious congregations, employers, schools, and other institutions have various interests. Thus, both types of representations are valuable for increasing the democratic quality of participation, as well as the available knowledge and the likely legitimacy of decisions.

For government agencies and other organizations concerned with 'citizen participation' in a general sense, including people from these categories may be sufficient for representation. However, those who are concerned with 'community participation' must give more specific attention to the identity of participants. To begin with, they must identify which communities have interests and who their members are. Then they must identify the specific groups and individuals within each community that care about or matter with regard to the issues at hand. This task entails identifying leaders (informal as well as formal) and people who are particularly knowledgeable (about issues, the community, and people in the community). With this understanding, those organizing decision making can include specific individuals who are representative of a community not just statistically and in terms of interests, but also in terms of perspectives.

There is no uniquely representative group of participants, but attention to these three types of representation will produce a group of considerable breadth. In this respect, the process of deciding who and what are to be represented and who can represent these people and positions matters. Traditionally, government agencies selected participants. In recent decades, a growing number of public and nonprofit organizations have consulted with community organizations, business associations, social service agencies, and others to consider together whom and what to represent and how. In other words, a representative process of selecting participants contributes to a representative process of deciding on issues.

In practice, it may be unclear at the beginning of a decision process who and what should be represented. Preliminary discussions of an issue may be necessary to bring issues to light and identify relevant parties to learn whom to represent and how. Moreover, representation is fluid. As a process proceeds, participants may identify new issues or interests that call for new representatives, and some issues and interests may recede in importance. As a practical matter, during deliberations of any great length, participants may drop out, and new participants would be necessary to continue representing certain groups, interests, or perspectives. The challenge at such moments, as throughout a decision process, is to be attentive to

who is affected by or interested in issues and to try to include persons who can speak for significant positions. For generating participation that is widely considered legitimate, this spirit matters more than any formula.

Enabling Participation: Predicaments of Low-Income Citizens

Even if a decision process is open to broadly representative participants and even if participants will all have significant and comparable power, citizens will not automatically take part. Participation has requirements and costs, including opportunity costs, and not everyone can afford to get involved. Above all, participation requires time; it depends on having discretionary time to spend in meetings and other activities, plus a willingness to forgo other uses of time that arise from responsibilities or bring pleasure, such as working extra hours, socializing with friends or family, watching television or movies, or helping children with homework. In addition, participation requires certain skills: normally (although not always) fluency in English; an ability to work with diverse other people, endure and work through conflicts, and come to a meeting of minds; an understanding of parliamentary procedure; and a conceptualization of a possibly long-term process of discussion and analysis as a means to solving problems. Further, participants must be at ease speaking in public, comfortable with their appearance and language, and patient with others who disagree and with a process that goes on without immediate solutions for problems.

Well-educated middle-class adults are most likely to have the time, skills, and experience needed for citizen participation. For many professionals, meetings, planning, and problem-solving processes are a normal part of their work, and they have much practice at collective decision making. They may already have considerable information about issues either from their work or from their reading or viewing of the media. If they need child care to attend meetings, they can afford it. Lower income adults, in contrast, are less likely to be able to participate. Economic need may require them to work evening or weekend hours that conflict with meeting times. Single parents do not have a spouse to look after children to permit meeting attendance, and they may be unable to pay for child care, although an extended family member may be available. Lower income adults may be self-conscious about their language or their dress, particularly if other participants are public officials or middle-class professionals. Although they may care greatly about the issues and have considerable information about local conditions, they may feel intimidated by how much more they imagine wealthier or better educated participants will know. They are likely to have limited practice with formal decision making, planning, and conflict resolution. Insofar as their time is scarce and daily needs are pressing, they may find the cost of the time required for participation unacceptably high and may be impatient with talk that does not produce immediate benefits. Whatever the socioeconomic background, people for whom English is not the first language may have difficulty participating in English discussion without interpreters.

Thus, representative participation depends on accommodating low-income and other citizens who face obstacles to participating. People are more likely to turn out when meeting times fit their schedules and locations are at sites where they feel safe and in friendly territory. People are more likely to attend when organizers have contacted and invited them through someone familiar and trusted in their community network. Child care makes it possible for parents to participate, and interpreters aid non-English speakers at meetings conducted in English. Providing clear basic information to all participants contributes to a sense of equality and competence on the part of those who start out with limited information, and bringing in experts helps similarly. Beginning a decision-making process with activities that both introduce participants to one another and describe the anticipated process and ground rules helps the less confident take more active part. Throughout, sensitive and explicit facilitation helps increase people's capacity to participate powerfully and effectively in reaching agreements.

Potentials and Limitations of Virtual Participation

Electronic communication has the potential to overcome some obstacles to face-to-face citizen participation, involve participants in complex activities, make participation more knowledgeable, make it more representative, and reduce power inequalities among participants. Communication technologies make it possible for citizens to interact without being in the same place or even acting at the same time. Most simply, electronic communication enlarges the opportunities for citizens to take part in or follow conventional face-to-face meetings. Individuals whose family responsibilities, work obligations, or health conditions prevent them from attending meetings can listen to, observe, and contribute to discussion electronically. Those who do go can blog reportage or commentary on events to others elsewhere. More complexly, communication technologies, supported by a growing number of online tools, make it possible for large numbers of citizens at face-to-face meetings or linked with Internet access to generate ideas, provide and develop information, express views on or debate ideas and issues, resolve conflicts, draft documents, prioritize options, and commit themselves to action together (Leighninger, 2011).

While electronic communication technologies allow virtual participation in decision making, they do not guarantee it. One constraint is the cost of hardware and some software. Public and nonprofit organizations may not be able to afford necessary equipment and material, and because individuals' computer ownership depends on their income, lower income citizens are least likely to have the consistent access necessary for ongoing participation. Moreover, some of the personal concerns that deter face-to-face participation also discourage virtual participation. Persons who are confident about their knowledge, views, and voice are most likely to take part. In addition, those who are comfortable with computer technologies, particularly those with more education and younger generations, are most likely to venture into virtual participation. Hence, as with conventional deliberation, outreach, especially personal contacts or contacts through community networks, is necessary to encourage and enable people to participate through unconventional means. In general, the complexity of online interaction, especially when participants do not see or know one another, requires careful planning, orientation of participants, and continuing explanation and

feedback to participants. Because virtual participation does not provide the emotional connection of face-to-face deliberation, individuals may feel limited motivation to join in or continue.

Virtual participation experiences have been mixed. Although the amount of communication has increased, often participants are generally the same who attend face-to-face meetings. Online technologies make it possible to obtain and generate considerable knowledge, but participants vary in their openness to new information about issues. Finally, while people may take part in discussions, surveys, games, and even drafting documents, only some are likely to become committed to making or implementing a decision. How virtual participation develops in conjunction with face-to-face participation depends on what technologies are developed, how people learn to use them, and what participation citizens want (Evans-Cowley, 2010).

Conclusion

Citizen participation in making public decisions that affect their individual and collective interests is a basic component of citizenship. However, public organizations may actively or inadvertently discourage citizen involvement, and citizens vary considerably in confidence that they have the political and intellectual authority to take part. As a result, those with higher income and education participate most commonly, and middle-class and white citizens are generally more active than lower income and racial or ethnic minority citizens. Thus, participants often do not represent a wide range of groups, interests, or perspectives, and higher income participants typically exercise more power over decisions than do lower income participants. Hence, deliberate effort is necessary to recruit participants and design processes to create decision making that is broadly representative, in which participants exercise similar power, and where participants act on shared, useful knowledge. Community organizing can draw public officials' and professionals' attention to these challenges and encourage them to address them.

Citizen Science

Hauke Riesch, Media & Communications, Brunel University London, Uxbridge, Middlesex, UK

Abstract

Citizen science (CS) refers loosely to participation in scientific research by members of the public. Diverse programs of CS reflect a host of different aspirations, goals, and ideals. Focusing mainly on the meaning of CS as coined by Bonney, the article will provide a brief account of the different types of projects that have variously been labeled CS, as well as some of the previous classification attempts. The main part will consist of surveying some of the problematic concerns that CS raises, such as the boundaries between lay and scientific expertise, the performance of CS in terms of science communication and other goals, and the ethical issues raised by volunteer research.

Introduction

The concept of citizen science (CS), or public participation in scientific research (PPSR), refers loosely to scientific or environmental monitoring projects involving participation of members of the public. In the mid-1990s, the term was applied by Rick Bonney (Bonney et al., 2009) to refer to a series of hybrid science and science communication projects that were then being pioneered by Bonney and his colleagues at Cornell University's Lab of Ornithology (CLO). These projects were designed to involve lay public participation in the gathering of scientific data, helping scientific research projects in obtaining new data as well as giving interested members of the public an opportunity, not just to learn more about ornithology, but to actively contribute to new and developing science. The initial concept has been widened and elaborated on both the science and the science communication sides, with new projects by the CLO and others attempting to involve members of the public in more activities and other stages of the scientific research process than just the data gathering (Bonney et al., 2009; Shirk et al., 2012), as well as formulation of a wider rationale for the science communication benefits of CS based on ideas that have emerged from science education studies (for example, Abd-El-Khalick et al., 1998, applied to CS at the CLO, see Trumbull et al., 2000; Brossard et al., 2005) that foreground teaching scientific methodology and the 'Nature of Science' as opposed to simply imparting facts. Moreover, learning about the Nature of Science in an experiential and practical manner away from the classroom has also been identified as particularly beneficial (Tuss, 1996).

Although the term CS started with the CLO as an innovative combination of participatory science and science communication, scientific and environmental monitoring projects that involved lay participants had been going on for some considerable time, especially in the field of ornithology (Greenwood, 2007; Toogood, 2011), to some of which the label CS has been applied retrospectively. These have evolved out of enthusiastic amateur natural history societies' activities, such as the annual Audubon Society Christmas Bird Count, which has been going since Christmas 1900 and is now describing itself as "the longest running Citizen Science survey in the world" (Audubon Society, 2013). Individual amateur contributions to science (such as the science of Benjamin Franklin) are often being cited as forerunners of CS (Silvertown, 2009), and although there is almost no relation any longer between the concepts and philosophies of CS in the CLO and eighteenth-century gentlemen scientists, it is probably fair to trace a direct conceptual lineage from interested lone amateur naturalists, to the establishment of amateur natural history societies in the late nineteenth century that draw on and attract a larger membership, and finally to contemporary participatory science research (Miller-Rushing et al., 2012).

CS projects that run along the lines of the CLO's programs have proliferated in recent years (the CLO maintains a non-comprehensive list of other CS projects at Citizen Science Central, 2013), and as the concept has traveled across different disciplines, institutions and countries, the emphases, ideals, and stated goals have often shifted and now produce a large variety of different types of CS projects that are rather loosely connected by an emphasis on combining participatory research with public engagement. The term CS has often been retrospectively applied to some of the predecessor amateur projects discussed above, as well as to other participatory science projects that have been developed independently of the CLO's philosophy, leading to a very diverse family of concepts that have been labeled CS. Added to this, the term was independently coined in the mid-1990s in the UK in an influential book by Alan Irwin (1995), where it refers more to the democratic participation of citizens in science and science policy (as part of the then developing 'upstream engagement' paradigm in public engagement studies). While there are some considerable overlaps between Irwin's and Bonney's concepts of CS (such as emphasis on public participation in science and the importance of dialogue between experts and the public), they are also fundamentally different in that they are intended to address different problems – combining research and science communication in one and producing democratically informed science policy in the other. Consequently, some authors writing within the Irwin tradition have expressed dissatisfaction with the other idea of CS as being more or less irrelevant to the problems they want to address (for example, Stilgoe, 2009).

As a result of the varying meanings attributed to the term, some commentators (including Bonney et al., 2009) now prefer to talk about 'PPSR'; whether for better or worse, CS has become the dominant term in which to describe public

participation in research projects, and this, in turn, has colored perceptions of it. While it appears that the different provenances of the term CS are not very widely known, a situation that can often lead to some confusion when scholars try to provide summaries of the philosophy behind CS, it also has produced some interesting hybrid philosophies of participatory science. These would, for example, emphasize the communal sense of ownership of the local environment that participation in CS could bring about, and which therefore can play a role in enhancing the policy voice of disadvantaged communities, important, for example, in developing countries where the voice of the local community in decision-making on environmental developments has often been marginalized, or which, like University College London's 'Extreme Citizen Science' project, aim to be "a situated, bottom-up practice that takes into account local needs, practices and culture and works with broad networks of people to design and build new devices and knowledge creation processes that can transform the world" (ExCiteS, 2013). Similarly such a hybrid conceptualization can be employed by the statutory sector as a way of simultaneously getting public help in monitoring, for example, the spread of tree diseases as well as providing the public with an avenue to input in any resulting policy (Forestry Commission, 2011). Even as part of the more science communication-oriented CS events, some mostly UK-based writers influenced by the Irwin tradition of public engagement, tend to foreground the value of CS as a democratic rather than scientific exercise (Hemment et al., 2011). While this variety of interpretations of CS is broadly being encouraged by most researchers as showcasing the innovative potential of CS, it has also led to some confusions and uncertainties over what CS should be and can achieve.

It has also led to several attempts to produce a more cohesive and workable classification of the various incarnations of CS. Shirk et al. (2012), developing a scheme they previously published in Bonney et al. (2009), distinguish between the degree of participation ("the extent to which individuals are involved in the process of scientific research") and quality of participation ("the extent to which a project's goals and activities align with, respond to, and are relevant to the needs and interests of public participants"). They thus arrive at five-idealized project models: *Contractual* projects (communities ask experts to conduct specific research, similar to the 'science shop' model, Leydesdorff and Ward, 2005); *Contributory* projects (public contributes data to projects designed by scientists); *Collaborative* projects (designed by scientists, but public also help with project design, data analysis, and dissemination); *Cocreated* projects (designed together by scientists and public); and finally *Collegial* contributions (members of the public conduct research largely independently of institutional science, such as the AIDS activists famously analyzed by Epstein, 1996).

Wiggins and Crowston (2011) distinguish between *Action* projects (grassroots projects "using scientific research as a tool to support civic agendas": p. 5); *Conservation* projects ("engaging citizens as a matter of practicality and outreach" to "support stewardship and natural resource management goals," often combined with "specific educational goals": p. 5); *Investigation* projects (focused on scientific research, with education a valued but not central goal); *Virtual* projects (where the interaction between researchers and public occurs online only); and finally *Education* projects (where the primary goal is science education rather than the science or the monitoring). There is some overlap between these categories, for example, in 'Zooniverse' series of the "Citizen Science Alliance" (Citizen Science Alliance, 2013) projects, which includes *Galaxy Zoo*, where the interaction with the public occurs only online, and which claims academic research as its primary goal, with the public engagement a welcome side effect.

The above typologies center around idealized project types based on the analysis of concrete examples they examined. We can alternatively draw up a map of CS projects that classifies them along several dimensions, such as number of participants, quality of interaction, and project purpose. Here we can observe that usually the quality of interaction decreases as the number of participants increases (because project scientists cannot give large amounts of individual attention to thousands of participants), leading to a trade-off between 'breadth' of and 'depth' of participation (Riesch et al., 2013). Two ideal typical projects lie at opposite ends of a spectrum, where the public contribution either amounts to very small individual contributions or fewer but higher quality and more engaged contributions.

Prainsack (2014) develops a classification of CS based on how the project is structured along six dimensions, or clusters of issues: Who has influence on setting the agenda; who participates and what do they bring to the project; how the project affects the communities and community identities, who decides what counts as success and how it is evaluated, openness and accessibility of the resulting data and publications, and finally project funding. Crucially, she argues that CS projects are not static and that therefore answers to these questions can be different at different stages of a project.

Boundaries and Expertise

The coming together of professional and lay expertise in CS opens up questions surrounding the definition and boundaries of expertise. Ellis and Waterton's (2005) ethnographic analysis of the networks in natural history monitoring projects that operate across the lay/expert boundary emphasizes that this boundary can be very fluid. The projects they analyze are slightly removed from CS projects designed as public engagement exercises that align more with the current CLO tradition, because the amateurs contribute specific lay expertise on a particular species or geographical location; they are involved because they can add unique and specific contributions through their own collection efforts, and therefore the project makes use of amateur experts rather than lay members of the public. In this case the blurring of the boundaries between experts and amateurs may be more obvious because the participating amateurs bring their own expertise to the table without wanting or needing to be educated by the project. In some 'depth' projects, the interaction is prolonged and in-depth so that the participants acquire expertise along the way, rather than necessarily producing a blurring of boundaries. The lay participants in such projects can also develop a discernible lay–expert identity through which they can challenge and engage in the policy process and the professional

expertise as a distinct group (for example, in Cornwell and Campbell's (2012) case study).

Amateur experts, however, can also participate in the 'breadth' educational projects. As scientists working on such projects have experienced, the projects often attract participants such as retired university professors or enthusiastic collectors who can "run rings around many of the scientists when it comes to sort of specifics of what they're interested in" (CS scientist quoted in Riesch et al., 2013). In this sense, the often hoped for aim of crossing boundaries between experts and the public can in some ways be realized, although the boundaries are clearly blurred to begin with.

'Breadth' and 'contributory' style CS projects, especially when intended explicitly as public engagement aimed at people who are not experts, however, might actually feel the need to emphasize the boundaries. In these CS projects, the professional expertise of the participating scientists is often one of the selling points that can entice people to participate. Participating members of the public expect to be guided by people who have expertise in the area and hope to learn science, scientific skills, and techniques. They are explicitly placed in a position of less epistemological and professional authority regarding the data they help produce. On the other side, the participating scientists, who often have years of training and paid positions within the academy or scientific research institutions, are ultimately the decision-makers who decide on which publicly contributed data are worth including and which directions the projects should take. In addition, they may be inclined to resist any blurring of the boundaries, as their professional identity is invested in the expertise they bring to the project. Consequently, greater public participation in the policy process as a sometimes hoped for by-product of educational CS is problematic, as it frames the science as a "ready-made set of issues, bounded and constrained, or pre-framed" (Toogood and Everett, 2013: p. 616), which consequently relegates the role of the public to 'nonnegotiable' and tightly constrained activities. Toogood and Everett thus argue that "the citizenship within such [projects] may actually reduce public awareness of political questions about biodiversity and frame relationships in ways which reinforce the distance between scientists and citizens" (p. 10).

Greater public participation in the actual scientific decision-making is envisaged by the 'cocreated' and in some cases the 'collaborative' CS projects that Shirk et al. (2012) describe and aim to encourage further. Yet these projects are still relatively rare within the universe of CS and the blurred boundaries in decision-making authority between experts and the lay participants may be a contributing factor to their relative scarcity. If intended as public engagement projects, there are inevitable questions to be asked whether cocreated projects can fulfill some or even most of the aims that variously sit behind public engagement: for example, as a way of creating public awareness of the scientific and/or environmental problems, cocreated projects rely on the initiative of people who are already aware of those problems. Similarly, when the aim is about teaching science and scientific practice, these projects also rely on participants with at least a minimal amount of background knowledge already, and although they have potential for educating participants beyond that level, this potentially limits the aim of bringing science to a broader public, regardless of their abilities and background knowledge. The value of cocreated projects thus lies in the science and is more likely to be closer to the CS projects analyzed by Ellis and Waterton (2005), rather than being particularly useful as public engagement tools. Therefore, the way a CS project sets itself up and defines its goals influences how the boundaries between the experts and the participants are defined and how they evolve with the project. While this is in itself not a bad thing, it limits some of the often rather lofty goals that proponents of CS often emphasize; instead of breaking the boundaries between participants and experts, and in the process teaching and/or inspiring the public about (a specific domain of) science, it looks more likely that a project can do either very well, but not really both at the same time.

One of the problems here is that, as described above, CS is a contested concept arising from two very different traditions, with a history that transitioned from enthusiastic amateur participation to public engagement with previously unenthusiastic participants; different goals, aims, norms, and values have been grafted together, and it seems unrealistic that just one particular setup can deliver them all at the same time.

For participating scientists, the data quality issue is seen as crucial, because on this the credibility of the resulting science will ultimately rest. This is not a judgment on the public's ability to gather useful data or the participating scientists' perceptions of that ability, but instead relates to the scientists' need to sell their work to a wider scientific community that may remain very skeptical about the scientific value of publicly gathered data. The peer-review system hinges on the ability of the participating scientists to persuade other scientists who may not share their enthusiasm about publicly gathered data. Consequently, it may also be difficult to report surprising or revolutionary results with CS (Riesch and Potter, 2014), because the default assumption may be that the data are to blame for anomalous results. Attitudes of the wider science community within the relevant field are probably one of the reasons why the scientifically most successful CS projects so far have tended to be in fields that already have an established history of amateurism: Astronomy, natural history (especially the subfield of ornithology), and biomedical sciences.

In order to address data quality, scientists in CS projects can adopt several strategies (see Riesch and Potter, 2014), including validating the data themselves, quizzing the participants on their background knowledge, or, probably most commonly, making the data gathering as easy as possible. For example, asking to count the number of spiders in a patch rather than asking participants to identify spider species, limits the data the project gathers to fairly simple questions, but which nevertheless can contribute to our scientific understanding by allowing a more geographically diverse survey than a small team of scientists could feasibly undertake themselves.

Scientists' and Public Motivations

Despite these issues, it is undoubtedly true that scientists often get excellent data from CS studies, and it is to be hoped that the continued success of these projects will pave the way for making publicly gathered data generally more acceptable within the wider scientific community. This would allow CS

projects to be broadened further to disciplines that do not traditionally partake in such projects, which, in turn, would help also to ameliorate some of the credibility issues.

Participation in public engagement is often by itself a motivator for scientists. Some get genuine enjoyment out of engaging with the public and also often feel a sense of duty (see, for example, Riesch and Potter, 2014). CS affords opportunities for scientists who are not experienced in public engagement to experiment without sacrificing their commitment to research, because when it is going well they can do both at the same time. As such, CS can be advertised as an attractive proposition for scientists, who can get both research and public engagement done at the same time leading to a 'win-win' situation. This situation can enhance personal motivations for scientists to participate in further public engagement projects; something that they are under increasing institutional pressure to do.

Studies that survey scientists' opinions about public engagement and science communication (for example, Burchell et al., 2009) often indicate that while they view such activities as important and often pleasurable duties, they also can cause a lot of problems when treated as an add-on to an already busy workload. Consequently, appropriate institutional reward structures need to be in place to encourage scientists to spend more time in engagement rather than (or as part of) their own research. However, while CS is sometimes seen as a natural solution to this problem (scientists can get both science and public engagement done at the same time), in practice, the right institutional support still needs to be in place to encourage participation in public engagement. Without it, even CS will fall short on the stringent demands for scientists' time, as scientists might feel that they get less research done in a CS project than they would have otherwise. Tasks performed by scientists on CS projects on one half of the equation can end up detracting from work in the other: some interviewees in Riesch et al. (2013), for example, felt that to give the public engagement side of their work the attention it deserves meant that they had to cram the science bit into their free time on weekends, evenings, and holidays.

There are two options on how to split the science and engagement work in a project: Either a scientist works on both sides part-time, or the task is split between dedicated scientists and science communicators within a project. In the former case, as outlined above, scientists often can feel that they are unable to give both sides of CS the attention and time it needs. Without adequate institutional support rewarding public engagement activities, this can have repercussions on their career progressions, because the amount of scientific research papers 'per pound' spent on the project will be less than in pure research projects, which some scientists have worried will look bad on their curriculum vitae when reviewed by faculty promotion or evaluation panels, or when they apply for other positions.

The other way of splitting responsibilities within a CS project is by hiring dedicated science communicators and public engagement professionals to interact with the public. This practice allows the scientists to concentrate on their scientific work, but has the obvious drawback that the public participants no longer get to interact with the leading experts, thus removing one of the primary selling points of CS.

Roy et al. (2012) have investigated the motivations in the statutory sector in promoting CS and similar activities to expand environmental monitoring and, sometimes more implicitly, to increase democratic engagement in science and environmental policy. Summarizing a series of interviews within (mainly UK) government agencies and departments, they list cost-effectiveness of CS environmental monitoring as particularly important, although as with the scientists studied by Riesch et al. (2013), discussed above, a minority of participants were worried about data quality. Overall, however, the utility of CS was seen as very large, with citizen scientists being able to collect more data and in more diverse places than government monitoring could on its own; this was, however, seen to bring risks and ethical issues with it as well (see below for further discussion).

For participating members of the public, motivations are found to be very diverse (for example, Raddick et al., 2010; Rotman et al., 2012). Their motivations depend on the type of CS project in question and can even vary over the course of a single project. They include the attractiveness of participating in real scientific research, the opportunity to learn more about science, contributing to the local community or to environmental conservation, or simply having a great day out. Even the possibly more time consuming and desk-based tasks, such as classifying galaxies for Galaxy Zoo, can be a pleasurable diversion for people who are interested in astronomy. The reasons for why people participate in CS are in many ways as diverse as the field of CS itself – different types of projects appeal to different people. For this reason Roy et al. (2012) argue that "it is not easy for users of data to design and develop a citizen science project that meets the needs of all volunteers," so that "projects must be tailored to match the interests and skill-sets of participants and understanding the motivations and expectations of potential volunteers is crucial to developing successful projects" (p. 5). The more hands-on CS programs that address relatively simple questions (as in the spider example above) are, for example, great for school kids and their teachers, who may be looking for a structured and meaningful activity for their classes. Galaxy Zoo, as an *investigation* project that is more interested in collecting scientific data than in the public engagement aspect (which is more of a side benefit), appeals to people who are already interested in astronomy but have so far not been able to pursue this interest scientifically. Projects aimed at local environmental issues might appeal to communities and community leaders who are interested in creating more ownership of the local environment, thus empowering the local community in their interactions around these issues with local authorities. These varying motivations can, and often do, intersect, leaving any particular CS project with participants who get involved for a variety of reasons.

Ethical Considerations

Although the ethics of CS have not been discussed extensively as a headlining focus of academic literature, practitioners themselves have thought at length about ethical issues, as is evident both in the number of blog posts written by CS scientists, and also by comments made in interviews with them

(see the discussions in Riesch and Potter, 2014). Ethics tend to be discussed in more detail when issues such as commercial exploitation of CS data come into play (see Bonsu and Darmody, 2008; Prainsack, 2014), which is a potential worry in some biomedical CS projects.

Ethical concerns can be raised in relation to both of the two main stakeholders in CS: the public and the professional participants. The former concerns mainly address two issues: ownership of data and remuneration for services given ostensibly for free. Firstly, the public's gathering of scientific data will give them a recognizable claim to ownership as coproducers of those data. Commercial exploitation of the data aside, the concerns relate to wider discussions over scientific transparency with data, but with CS such issues are even more urgent because the direct involvement of citizens as data producers rather than just funders (as taxpayers) of scientific research. These problems may be more easily solved by ensuring that the data and resulting research papers are made publicly accessible, though there may also be practical obstacles such as the cost of publishing open access or potentially sensitive personal information in the biomedical projects. Here discussions within the wider open access movement apply.

Related to this issue though is a second, slightly more intractable, one. Members of the public participate in CS usually without being recompensed, at least monetarily, for their time and effort. For example, criticisms made of *Big Society*, a recent UK policy initiative that aims to increase public volunteering, suggest that it is a matter of outsourcing public sector responsibilities onto unpaid volunteers in the guise of a local empowerment rhetoric (Kisby, 2010).

Instead of paying them in money, CS programs aim for other ways to compensate their participants. In the case of projects aimed at public engagement, such compensation comes in the form of an opportunity to learn, interact with scientists (although see the provisos above), and the enjoyment they get out from participating. Managers of some projects, such as Open Air Laboratories (Davies et al., 2011), are very conscious of the issue, to the extent that they discourage use of the term 'volunteer' for public participants. Although it would be unfair to claim that CS exploits free public labor, the question can still be raised over whether such nonmonetary compensation is enough. The participating experts and scientists are being paid a salary, even if they themselves report that they also getting an enormous amount of enjoyment out of CS projects. Although it can be argued that the participating experts have the experience and education to command such monetary compensation, it opens up the boundary issues discussed above, as CS moves even further away from the ideal that some people see in it of breaking down barriers between professionals and amateurs. Instead of a cooperative collaboration of equals, CS clearly delineates between, on the one hand, the scientists with authority over the direction of a project, who have the qualifications and expertise, and who get paid for their time and get to develop professional careers through scientific publications, and, on the other hand, public participants who are given very little epistemic authority, certified expertise, and monetary compensation.

The reliance on participants' free time, effort, and goodwill also has repercussions on project development and planning itself. Firstly, there may be the effect of public fatigue from being asked to do voluntary work, which can make recruitment of enough participants difficult. Secondly, especially in more small-scale projects, the participating scientists may not be able to rely on volunteers to deliver to targets, or even turn up on time, which can become problematic when strict time frames are involved.

Another form of remuneration that scientists receive for their work on CS is the professional recognition (or symbolic capital) that comes from authoring the resulting scientific papers. Theoretically, the authorship of scientific papers can be extended to all participants who produced data for it, but as a practical matter this is often seen to be impossible, at least for the large-scale 'breadth' projects, where participants number in the thousands. 'Depth' projects, where public participants are fewer and more engaged, offer more obvious instances where coauthorship of the resulting papers may be offered; similarly, such recognition may be possible in those projects that involve extensive public participation, when selected participants have significant input into new discoveries (such as Galaxy Zoo, Clery, 2011).

Finally, CS raises ethical concerns on the science side, both for individual scientists and sometimes for science at large. Asking members of the public to do something for free may end up limiting opportunities for scientists. This may be more of an issue for individual scientists without steady employment, such as postdocs and graduate research students, who might see potential jobs being 'outsourced' to volunteers, an issue that has been at least jokingly mentioned by a postdoc who Riesch and Potter (2014) interviewed. While this may be less of a problem for the 'breadth' projects that rely on large surveys in which many individuals produce small amounts of data, some of the more engaged interactions in the 'depth' projects may intersect with the ethical problems that have been highlighted with scientific research institutions that rely upon unpaid internships (Perlin, 2012). Concerns about such internships were raised that university research performed by unpaid research assistants may crowd out professional scientists – mostly the postdocs who are one of the most financially and professionally insecure groups within the scientific hierarchy. More insidiously, perhaps, the CV-building opportunities afforded by these internships may end up being open only to students who have independent financial means. Parallel to the debates that are going on over unpaid internships within other aspirational professions such as journalism or the banking sector, the concern is raised that poorer people are being denied a route into the profession.

As CS has evolved from the amateur science performed by voluntary membership organizations of the late nineteenth century, which, in turn, derived from the time when science was largely an unpaid hobby of gentlemen with independent means, we may want to look back at the positive aspects of the professionalization of science: By making science a paid profession, the developments from the nineteenth century have opened up science to a wider portion of the population and the vast talent pool of those who cannot pursue science in their spare time. As many commentators have done, we can treat CS as an inheritor of the earlier amateur science tradition, but we can add that it also needs to confront this heritage and to ask itself potentially uncomfortable questions about the actual end effect of what it is trying to do, especially since this effect is

almost the exact opposite of the democratic and progressive intentions of many of its proponents.

Abstract

This article locates anthropology's arrival to citizenship studies and explores the peculiarities of anthropological approaches to citizenship, their contributions to theorization of citizenship as well as their limitations. It argues that the practice-based and processual understandings of citizenship in anthropology put a strong emphasis on the shifting meanings, everyday practices, and the varying and unpredictable sites of citizenship, which in turn makes ethnographic research central for citizenship studies. Finally, it situates anthropology's valorization of 'citizenship from below' within the context of neoliberal governmentality and argues that without 'nonlocal ethnography' anthropology's contribution to citizenship studies remain limited.

Introduction

Citizenship studies always had a solid place in political science and legal studies. However, since the 1980s, there has been a flourishing interest in the concept of citizenship and citizenship arrangements beyond their classical disciplinary bases. Anthropology has been a latecomer to the studies of citizenship. In this article, instead of providing an overview of the vast literature of citizenship studies, I will focus on anthropology's arrival to citizenship studies, on the peculiarities of anthropological approaches to citizenship, and on their contribution to the conceptualization of citizenship as well as on some of their limitations.

The conventional liberal understandings of citizenship are state-centric. They formulate citizenship as a form of (legal) relation between the individual subject and the (nation-) state, as well as a relationship of membership and belonging to a political community, which establishes the ground for the rights and responsibilities. Here, nation is the envisaged political community. The conventional approach to citizenship is a universalized and an abstract one, where legal status and the state are central to its conceptualization. Contrary to sociology, nation-state never loomed large in anthropology, and citizenship was not a central focus of interest for anthropology until the unmooring of citizenship studies from the state-centered frames of liberal and normative approaches. The more scholars documented the disaggregation of citizenship and citizenship rights from the nation-state, the more scholars started to question the conventional conceptions of citizenship. They challenged the hegemonic conceptualizations, which understood citizenship primarily as an issue of formal, legal status. They highlighted those cases which revealed that the nation-state cannot be taken for granted as the source of legitimacy and seedbed of individuals' rights. Several scholars drew attention to the fact that despite the lack of the formal, legal status of citizenship, people within the nation-state enjoyed social, economic, and cultural citizenship rights legitimated by transnational, supranational, and human rights regimes (Soysal, 1994; Bauböck, 1994). Similarly, they noted that citizenship was variegated within the nation-state: not all people who are legal citizens receive the same treatment from the state or are able to claim the same rights.

There are often categories of people who are legal citizens according to the laws of a state yet face various forms of exclusions and the denial of civil rights because they are not considered to be truly part of the nation. These categories include members of lower social classes – both rural and urban – and persons who are racialized or gendered in ways that put them outside the body politic (Marshall, 1964; Yuval-Davis, 1997). These distinctions between legal status and rights illustrated that legal status neither guaranteed the exercise and practice of rights for all those who had this legal status nor that these questions of inclusions and exclusions were static.

In the context of increasing salience of frames and practices of dual, multiple, and transnational citizenship (Goldring, 1998; Glick Schiller, 2005; Bauböck, 1994; Caglar, 2004; Levitt, 2001), the failure of those universalized perspectives of citizenship (which were developed at a time of the hegemony of nation-state in particular parts of the world) to capture the current practices of claim making, participation, and membership became more apparent. It became increasingly more difficult to operate with a concept of citizenship based on a historically constructed isomorphism between nationality and citizenship and which thus disregards the salience of different scales that function as the foundation of the political community upon which the source of rights and membership are grounded (Neveu, 2005; Clarke et al., 2014; Holston, 2008; Sassen, 2001).

Simultaneously, there was an increasing proliferation of forms and sites of citizenship such as 'environmental,' 'sexual,' 'indigenous,' 'post-national,' 'cosmopolitan,' 'multicultural,' 'transnational,' 'intimate,' 'diasporic,' and 'urban.' This pluralization also drew attention to the fact that there were different kinds of communities other than nations upon which claims were based. Consequently, the taken-for-granted connections between rights and states, the static nature of rights, seen as if they were possessions, as well as the universalizing conceptions of citizenship came under scrutiny. Rather than a static view of citizenship, which is inscribed into formal laws, a processual understanding of citizenship with an emphasis on its 'unfinished' nature came to the fore (Balibar, 2003). Anthropological approaches to citizenship followed these perspectives, which underlined the contextual, processual, practice-based, and contested character of citizenship. Ethnographic studies

focused on the citizenship practices and relations in concrete places and times, highlighted the relational, agency-based, and the contentious character of the citizenship within a wider array of mainly state actors. Contrary to the universalizing and normative understandings of citizenship in political sciences, which approached citizenship in a kind of 'empirical void' (Conover et al., 1991) anthropologists' work documented the practices and sites of citizenship and the varying and contested meanings citizenship took in diverse but concrete contexts. Anthropological studies of citizenship, with their emphasis on the diversity of meanings citizenship takes in different contexts contributed to the further "unlocking" of "citizenship from its focus on it as a legal/juridical and political status as corpus of rights and obligations and responsibilities…" (Clarke et al., 2014: 12).

Nation-State Sovereignty, Citizenship, and Migrants

Several scholars noted the disruption of territorial and judicial authority in nation-states in the context of globalization and addressed the contradictions of the nation-state sovereignty-centered citizenship models in our world (This section partly draws on Glick Schiller and Caglar 2008; 332–336). They draw attention to the increasing number of people who live in overlapping or multiple jurisdictions or to people who exercise social, economic, and cultural rights despite the absence of legal citizenship (Soysal, 1994; Sassen, 2001; Benhabib, 2007; Ong, 1999). The meaningfulness of nation-state scale as the suitable frame to capture the current citizenship arrangements is put into question. The weakening of the grip of state-centric citizenship models facilitated the arrival of practice-based processual approaches of anthropology in citizenship studies. Within this context, migrants as groups of people who exemplify the decoupling of rights and legal status as well as those subject to multiple jurisdictions become an important category of people to think with the changing dynamics of state-sovereignty and citizenship.

Consequently, the decoupling of formal rights which people possess as legal citizens and the social and cultural rights people practice without the legal citizenry became an important arena to discuss the problems with the nation-state and legal rights-centric approaches to citizenship (Soysal, 1994; Holston, 2008). Although legal citizens are often denied full civil rights, many states grant a range of rights to those who reside legally in a state but do not have legal citizenship and may even be ineligible to become citizens. As Soysal (1994) has emphasized, although they lacked formal membership in the host nation, migrants and their descendants often have been accorded various social, economic, civil, and cultural rights. The access accorded to these migrants has revealed the increasing disjuncture of formal and substantive citizenship rights and according to her, the sources of these substantive rights are anchored in human rights regimes rather than the nation-state.

Benhabib (2007), on the other hand, traces the source of these discrepancies and the disjuncture between territoriality and jurisdiction to cosmopolitan laws.

Ong (1999) analyzes the varying jurisdictions and the flexibilization of citizenship as part of the requirements of a particular kind of capitalism in the context of global economy. Like others, she also addresses the inroads made into state-sovereignty, but she does not see these heterogeneous political spaces, which are subject to differential regimes of rights and obligations ('graduated sovereignties'), as the indicators of the weakening of state-sovereignty. On the contrary, she approaches them as part of strategies of governmentality through which the state reconfigures its power in the context of global economy. According to her, destabilization and flexibilization of citizenship by deploying different citizenship regimes in the same state territory are part of the changing relations between nation-state and the cultural logics of capitalism. Moreover, this is not a weakness but a strategy for the disciplining of citizen-subjects.

In order to capture the social dynamics of participation and membership of those who do not have legal citizenry, anthropologists of citizenship increasingly have examined the practices and performance of citizenship rights. These discussions have enmeshed with anthropologies of migration, which focused on migrants' practices of social and political participation and membership. They have also explored migrants' vernacular notions of citizenship with a particular emphasis on the local, informal, and the community-based nature of their practices of political participation.

Moreover, scholars have expanded the concept of citizenship by distinguishing between cultural and social citizenships. Rosaldo and Flores (1997: 57) refer to cultural citizenship as "the right to be different with respect to the norms of the dominant national community, without compromising one's right to belong in the sense of participation in the nation-state."

However, cultural citizenship focuses on identities and the diversity of cultural practices, but it does not address the way in which persons who are not citizens participate in the common social, economic, and political life of a specific state and claim rights in these multiple domains. In order to address these practices and claims that facilitate the daily participation in the social life of a locality and generate claims and assertions of belonging that are not confined to the politics of difference and the cosmology of identity politics, scholars have begun to speak of social citizenship.

Social citizenship differs from legal citizenship because of the lack of mesh between formal citizenship and the allocation of rights, benefits, and privileges. When people without official membership make claims to belong to a state or to a city through collectively organizing themselves in order to protect themselves against discrimination, or receive rights and benefits from a state or local authorities, or make contributions to the development of the place of settlement and the life of people within it, they are said to be social citizens. Social citizens assert rights to citizenship substantively through social practice and social presence rather than law (Glick Schiller and Caglar, 2008). This approach to citizenship, which locates citizenship in horizontal social relations is concerned with the performative dimensions of membership beyond the domain of legal rights, and defines the meaning and practices of participation and belonging as it is displayed within the public sphere (Holston and Appadurai, 1999).

Moreover, the emphasis in social citizenship is on the horizontal ties between the people rather than the vertical ties between the individual and the state as formulated in the

formal citizenship (Caglar, 2004). In social citizenship, citizenship practices are located in social relationships. Although social citizenship scholarship operates with an understanding of the social that has been conceptualized almost solely within the conceptual network of social rights that facilitate the full participation of citizens and noncitizens of a polity, some scholars have been drawing attention to the necessity of recasting the meaning of the 'social' in citizenship. Isin (2008) and Brodie (2008) plea for using the broader meaning of the word social that captures its Latin origin *socius*, which refers to fellowship and companionship. In this sense social citizenship refers to "the dense fabric of relations that constitute humans as social beings who coexist with their fellow beings in and through conflict and cooperation that undergird norms, laws, and customs" (Isin, 2008: 282). This is an important point of entry to address sociability and conditions of coevalness and contemporaneity among the members of society beyond legal status.

Many people claim rights in a state and act within its institutional and governmental processes not only without formal citizenship but also while they reside in another state. 'Transnational' or 'transborder' citizenship is used to denote peoples' (mostly migrants') simultaneous participation in citizenship practices within and across borders of nation-states (Aleinikoff and Klusmeyer, 2001; Bauböck, 1994; Faist, 2000; Caglar, 2004; Glick Schiller, 2005; Goldring, 1998). Underlying these transborder practices is some type of claim to membership, rights, and voice in more than one state.

Most of the research and discussion of multiple membership claims and transborder citizenship has focused on migrants' social citizenship practices that connect a new land of settlement and a homeland. In these instances, migrants who become citizens of a new state, continue to influence their homeland, even if they have abandoned their legal citizenship rights. (Caglar, 2004; Levitt, 2001; Glick Schiller, 2005). Migrants who live their lives across borders may claim rights and membership in places where they do not have legal citizenship or in places where they no longer hold full legal citizenship.

These practices that are not necessarily based on formal arrangements of citizenship operate at the disjuncture between legal and substantive citizenship. However, these transnational citizenship practices are shaped in interaction with a number of actors, ranging from state to supranational and global institutions (Goldring, 1998; Caglar, 2004).

Although human rights regimes provide an important basis for social citizenship claims, some others make such claims of social inclusion, participation, and sociability in the name of religion. Religious claims and networks can foster social citizenship. In these instances migrants claim rights to residency, social benefits, respect, and moral and political leadership on the basis of their membership in a global religious project and the social field created by its networks of organizations (Levitt, 2003; Glick Schiller and Caglar, 2008). Scholars who examine migrant (social and political) participation that are anchored at religious organizations, homeland associations, or at seemingly apolitical sites like dance/music associations approach these sites as the new spaces of citizenship from below that function beyond the formal venues of citizenship (Reed-Danahay and Brettell, 2008; Hamidi, 2003).

Citizenship, Alterity and Margins

Citizenship provides the ground to distinguish between citizens and aliens. Scholars of citizenship note that margins and alterity are crucial in the constitutions of citizenship and they argue that the excluded, their practices, and their modes of exclusion are central to the constitution of citizenship. Citizenship creates and is created by its alterity (Isin, 2002). Consequently, within this relational understanding of citizenship and alterity, those who fall into the category of excluded, that is the undocumented, refugees, and the migrants come to the fore as the major constituents of citizenship (Balibar, 2003; Sassen, 1998; Isin, 2002; Holston, 2008; Varsanyi, 2006; Rajaram and Arendas, 2013; Caglar and Mehling, 2013). Building upon this understanding of citizenship, where margins are constitutive of the whole, Clarke et al. (2014: 49) argue for "recentering of citizenship around spaces, sites, and practices that are often described as marginal." Scholars argue that citizenship is defined at its margins because the inclusion of the excluded leads to a rearrangement of the existing structures and to a disruption of the taken-for-granted assumptions upon which the hegemonic understanding of citizenship at that place is based. When the excluded, like the undocumented, refugees, or the poor claim or demand their rights to be included as valid members of the society through informal, unofficial, and/or illegal venues, scholars refer to these practices as 'insurgent citizenship' (Holston, 2008; Varsanyi, 2006). The insurgency of such practices lies in their transformative capacity of social body as well as body of politics, as the granting of such rights to the excluded results in the formation of new categories, laws, and political subjects, in short, in the remaking of citizenship (Clarke et al., 2014: 171).

Isin (2008) refers to such insurgencies as 'Acts of Citizenship.' This is a concept that allows us to capture the moments when subjects constitute themselves as those making claims, asserting and imposing rights and obligations beyond the ones granted to them by law (2008: 5–6). According to him, acts of citizenship 'contest' habitus and citizenship practices by grounding their legitimacy and entitlements not in the existing legal and social frames but in unfamiliar or new grounds, and they introduce rupture to the given order. By instantiating a crack in the institutionalized order of things they become part of contentious politics. Within this perspective it becomes possible to approach sites as being constitutive of the acts of citizenship and explore the impact of the materiality of sites in the formation of such acts (Caglar and Mehling, 2013).

Anthropology and 'Citizenship from Below'

The common ground of anthropological approaches to citizenship is their emphasis on 'politics from below' and on the venues of participation and rights beyond the official forms and state-endorsed rights (Nuijten, 2013: 11). In summary, what differentiates anthropology's take on citizenship from other disciplines is an approach to citizenship as a set of practices mostly located in everyday life; as a process; as belonging and membership anchored at a political community beyond the national scale; as webs of meaning; as horizontal

relations located in social relations with the others and as subjectivity.

All these indicate a broader understanding of citizenship. Rather than seeing it as a relation to a state, where the exercise of political rights derived from the legal status are central, anthropologists view citizenship as a set of practices that enable the participation in social and political life and as a venue for sociability. Here, the emphasis is on the people's everyday experiences of citizenship and on the formation of their subjectivities and their political agency through their claim-making processes within a particular historical and political context (Neveu, 2005; Nuijten, 2013). This contextual and processual understanding of citizenship, which is always in the making, is very different from the static understanding of a liberal conceptualization of citizenship where the rights are seen to be possessions of the individual subjects that are endorsed by the state (Neveu, 2005). However, the most differentiating aspect of anthropological understanding of citizenship lies in the scale of the political community, which establishes the contingency of political membership, belonging, as well as the ground through which the subjectivities are constructed. Rather than equating the political community with the nation, anthropological studies of citizenship draw attention to the different kinds of communities upon which claims are based and membership and belongings are forged. These could be city-based communities, they could be even trade unions as Lazar shows in her study on citizenship and political agency in Buenos Aires, but they could also be border-crossing cosmopolitan or transnational communities (Lazar, 2013; Lazar and Nuijten, 2013). In her study of slum upgrading projects in Brazil, Nuijten (2013) shows how subjectivities, political belonging, and the political community are mutually constituted through the slum dwellers' claim-making processes that are entangled with the creation of a new landscape of empowerment and disempowerment. All these studies underline how citizenship is reworked in daily practices and discourses.

Most importantly, anthropological studies of citizenship put a strong emphasis on the language, vernacular, and the repertoires of citizenship. The language of rights and responsibilities vary. What people understand from rights and responsibilities at a particular place, and the meanings people give to their relationships with the state and with the bureaucracy are central to anthropological studies of citizenship practices (Ouroussoff and Toren, 2005; Stack, 2013). As Ouroussoff and Toren (2005: 209) formulate "[F]for us as anthropologists, the issue is not what model of citizenship we should endorse, but rather what ethnography can do to analyze how these key categories – citizenship and culture – are being constituted anew (and in this process transformed) in the practice of their everyday lives by particular people(s) in particular times and places. The challenge of contemporary ethnography is to render analytical categories people use to talk about themselves, their lives, and their ideas of the world."

The heterogeneity of citizenship's sites, settings, spaces, and scales, which the anthropological studies of citizenship document, shows us that anthropological studies underline the fact that sites and spaces of citizenship and politics could not be known a priori as they vary in space and time. Designating these sites is an empirical question and requires a contextualized analysis to explore in which specific sites, citizenship acts are anchored and in what specific ways. As Clarke et al. (2014: 5) aptly underline "citizenship always takes specific forms that are outcomes of sets of processes and are related to specific political projects, particular social contexts and distinctive cultural configurations." Within this framework, ethnographic research becomes central to the analysis of citizenship practices.

In short, anthropologists approach citizenship as a process from below, thus as a grassroot political process. Given the anthropologists' emphasis on the primacy of everyday interactions for the constitution of individuals' subjectivities, 'everyday citizenship' comes to the forefront as a crucial aspect of anthropological approaches to citizenship (Holston, 2008). Citizenship from below, which characterizes the anthropological approaches to citizenship, then refers to the experienced, lived citizenship that expresses the everyday realities of political belonging (Nuijten, 2013: 11).

Citizenship and Cities

Several scholars who approach citizenship beyond the state-centered liberal model argue that, in the context of globalization, cities emerge as the site and the context in which residents constitute their claims and entitlements and the meaning and practice of citizenship. Cities, rather than nation-states become the axis and the locus for political belonging and membership. Thus they replace states as the primary reference point in citizenship practices. Rather than the legal status, they argue, residence is pivotal for rights and entitlements (Sassen, 2001; Bauböck, 1994; Benhabib, 2007; Varsanyi, 2006). Several ethnographic works on citizenship followed suit. However, no matter how cities become crucial units of governance and strategic sites for generation of wealth and political operations, in the context of neoliberal globalization it is important to approach cities not as entities having a life of their own, but situate the dynamics of urban economies, politics, and culture within global networks of power hierarchies. Especially in the neoliberal context of entrepreneurial cities and governmentality, the valorization of cities as alternative grounds of citizenship practices and entitlement in counterpoint to state-based arrangements might require caution. In reference to the workings of the neoliberal state, Rose and Osborne (2000: 108) draw attention to new forms of governmentality through 'citizenship games.' These games refer to practices, which constitute its players; that is, the citizens with a particular kind of conduct, so that citizens by playing their own parts become part of the games that govern them.

In the context of the neoliberal state where the state shares its powers of control and discipline with other actors and agencies, Rose and Osborne argue that "[C]itizenship is no longer primarily realized in relation with the state," instead through "a set of dispersed and non-totalized practices within which games of citizenship must be played" (2000: 108). Moreover, moving away from an understanding of citizenship as possession to citizenship as capacity is part of the new forms of governance of the neoliberal state (2000: 108). In the context of enabling and constraining the workings of the

neoliberal state, which functions through the activation of powers and agency of citizens, the distinction between state and civil society as well as the clear distinction between 'citizenship from above' and 'citizenship from below' become blurred. Furthermore, communities are the new ethical spaces through which new forms of governmentality operate (Rose and Osborne, 2000). Thus, neoliberalism revives communities. This kind of framing of the workings of the neoliberal state, cities, and governmentality enables us to situate the valorization of 'citizenship from below' and communities in anthropological approaches to citizenship anew.

It is true that anthropologists of citizenship played an important role in moving discussions of citizenship from the normative and the institutional straitjacket of universalized models and put the processual and relational character of citizenship at the center of their studies. However, in the context of neoliberal valorization of imaginaries and practices of community livelihood, anthropologists' emphasis on the local practices of communities as the primary sites that facilitate participation and empowerment, and as sites of citizenship practices and sociabilities becomes problematic. Several works on neoliberal cities have illustrated that the recreation of communitarian obligations and allegiances are crucial for neoliberal governance and especially for that of cities. From this point of view, cherishing communities as sites of mutuality and sociability takes a different meaning once we contextualize such approaches within the novel forms of neoliberal governmentality and governance of cities.

In Conclusion: Everyday Citizenship and Nonlocal Ethnographies

Like all subjectivities, citizenship is also mediated. In order not to be carried away by an over-fluid understanding of citizenship, it is important to refer to the structures and institutions within which subjects are constructed and within which this mediation takes place (Clarke et al., 2014). It is crucial to focus on the meanings of citizenship and the citizenship language, through which demands are articulated and claims are made. However, these meanings are enabled within the constraints of a set of legal, political, and institutional conditions rather than being the outcome of interplay between citizenship and culture. Moreover, the conditions of possibility of meanings and practice cannot be grasped when we remain confined to the descriptions of the everyday practices.

In order to underline the mobilizations and the shifting meanings of citizenship and its plastic capacity of articulation to varying political projects in different places, Clarke et al. (2014: 6) designate citizenship as a keyword in the sense of Williams (1983). By identifying it as a keyword, among other things, they underline the constitutive, productive, and the performative force of citizenship languages and their mobilizing power for social and political action. In fact, citizenship languages, with an imagery and a repertoire, closely tied to human rights discourses very often find their place in the formulation of demands and consequently in the mobilizations construed through these claim-making processes (Nuijten, 2013). However, no matter whether or not their meanings shift in their local use, citizenship languages and the repertoire of human rights are part of global processes of claim making that can neither be confined to that particular locality nor be captured as part of general flows of ideas and discourses. Citizenship languages and repertoires are mediated within a set of institutional and discursive networks and this process cannot be fully grasped through ethnographies of everyday practices.

In order to study the global processes in which relations are mediated between actors that have not been in direct contact with each other, Feldman (2011) argues for a nonlocal ethnography that will go beyond the participant observation bias of ethnography, which is often anchored in the valorization of everyday life. He differentiates connections and relations. While the former involves immediate direct contact, the latter refers to indirect mediated contact. "Nonlocal ethnography" deals with relations and "addresses how people are specifically related when they are not connected in global configurations of power" (Feldman, 2011: 380). This is a similar search for an ethnographic entry to study global dynamics relationally, so that we can reveal, expose, and explain the connections between faraway yet intimately related developments and integrate them into the core of anthropologists' work (Miraftab, 2014). However, in order to see "how seemingly independent processes and locations are intimately connected with each other," we need to situate them into hierarchically structured relationships (Miraftab, 2014). This requires an analysis of the processes and relationship that shape the power structures connecting these places, which urges us to go beyond ethnographies located in everyday life and confined to participant observation. It is true that with its attention to personal narrative and to the contextualized enactments of citizen practices in everyday life, ethnography offers an important entry into the analysis of citizenship practices, their shifting meanings, and the formation of subjectivities beyond the legal grid of citizenship models. It is also true that by exploring the agency-based dynamics of everyday citizenship, anthropological studies on citizenship provide an important intervention to the taken-for-granted scale of liberal understandings of citizenship. However, without a nonlocal ethnography that would allow us to relate the dynamics between everyday citizenship practices and networked institutions of power, such interventions of anthropologies of citizenship fail to grow into their explosive capacities.

Abstract

Historically, the distinctive core of citizenship has been the possession of the formal status of membership of a political and legal entity and having particular sorts of rights and obligations within it. This core understanding of citizenship goes back to classical times and coalesced around two broad understandings of citizenship stemming from ancient Greece and Imperial Rome respectively that later evolved into what came to be termed the 'republican' and 'liberal' accounts of citizenship. This article first examines these two classic views, then looks at how they changed during the Renaissance and Reformation, and finally turns to the ways the two were to some extent brought together following the American and French Revolutions within the liberal democratic nation-state.

Historically, the distinctive core of citizenship – at least within the Western political tradition – has been the possession of the formal status of membership of a political and legal entity and having particular sorts of rights and obligations within it that distinguish one from being either a subject or a casual visitor, on the one hand, or performing some other noncivic social role, such as a friend, a neighbor, or a Good Samaritan, on the other. Different conceptions have offered different views as to what the criteria of membership should be; the nature of the political and legal institutions to which a citizen belongs; the content of their rights and duties; and the character of the norms and attitudes citizens require to exercise and fulfill these civic entitlements and obligations. However, all agree that citizenship is a political and legal artifact that creates a condition of civic equality among those who possess it with regard to the prerogatives and responsibilities it bestows and requires.

As J.G.A. Pocock (1995) has argued, this core understanding of citizenship goes back to classical times and coalesced around two broad understandings of citizenship stemming from ancient Greece and Imperial Rome respectively that later evolved into what came to be termed the 'republican' and 'liberal' accounts of citizenship. In what follows, we shall first examine these two classic views, then look at how they changed during the Renaissance and Reformation, and finally turn to the ways the two were to some extent brought together following the American and French revolutions within the liberal democratic nation-state.

The Two Classic Conceptions

The canonical text of the Greek version of citizenship is Aristotle's *Politics* (335–323 BC) with ancient Athens the model. Aristotle regarded human beings as 'political animals' because it is in our nature to live in political communities – indeed, he contended that only within a *polis* or city–state could human potential be fully realized. However, he believed people played the roles appropriate to their natural station in life, with only some qualifying as *politai* or citizens. Though neither the qualifications Aristotle deemed appropriate for membership of this select group nor the duties he expected of them are regarded as entirely suitable today, they have cast a long shadow over the history of citizenship and their inner rationale still underlies much contemporary thinking.

To be a citizen of Athens it was necessary to be a male aged 20 or over, of known genealogy as being born to an Athenian citizen family, a patriarch of a household, a warrior – possessing the arms and ability to fight, and a master of the labor of others – notably slaves (Finley, 1983). So gender, race, and class defined citizenship and many of the main later debates have turned on how far they continue to do so. As a result, large numbers were excluded: women, though married Athenian women were citizens for genealogical purposes; children; immigrants or 'metics' – including those whose families had been settled in Athens for several generations, although they were legally free, liable to taxation and had military duties; and above all slaves. It is reckoned that the number of citizens in Athens fluctuated between 30 000 and 50 000, while the number of slaves was of the order of 80–100 000. Therefore, citizenship was enjoyed by a minority, though a substantial one. Yet, this was inevitable given the high expectations of citizens. For, their capacity to perform their not inconsiderable citizenly duties rested on their everyday needs being looked after by the majority of the population, particularly women and slaves.

Aristotle described citizens as those who "rule and are ruled by turns" (Aristotle, 1988 [335–323 BC]: 1259b1). Though the duties involved differed between polities and even different categories of citizen within the same polity, at some level citizenship involved "the power to take part in the deliberative or judicial administration" (Aristotle, 1988 [335–323 BC]: 1275b1) In Athens this meant at a minimum participating in the assembly, which met at least 40 times a year and required a quorum of 6000 citizens for plenary sessions, and, for citizens aged over 30, doing jury service – again, a frequent responsibility given that juries required 201 or more members and on some occasions over 501. Though jury service was paid, jurors were chosen by lot from among those who presented themselves to discourage both its becoming a regular income and jury packing. In addition, there were some 140 local territorial units of government, or *demes*, with their own *agorai* or assembly points for public discussion of local affairs and passing local decrees.

Meanwhile, many citizens could not avoid holding public office at some point. Apart from generals, who were elected by the assembly and could serve multiple terms if successful, public officers were chosen by lot, served for 1 or 2 years maximum, with key roles often rotated between office holders. These devices aimed to increase the likelihood that all citizens

had an equal chance of exercising political power, with the short terms of office and the checks operated by the different bodies on each other ensuring this power was severely circumscribed. Yet, though there were no career politicians, citizenship itself, if one adds military service and participation in local affairs, was a fairly full time occupation.

Athens was unusual among Greek city-states in being so democratic. Indeed, Aristotle, who periodically resided in Athens but was not born there and so was not an Athenian citizen, expressed a personal preference for systems that mixed democracy with aristocratic and monarchical elements. However, even in those systems, citizenship remained fairly onerous. Like Plato, Aristotle esteemed the austere citizenship code of Sparta. By contrast to Athens, where the arts, philosophy, and leisure were much admired, Sparta emphasized military service above all else. Male children were separated from their families aged 7, subjected to a rigorous training, and thereafter attached to a 'mess.' Given they still had to attend the Assembly, Spartan citizens became even more permanent public servants than their Athenian counterparts. In fact, it was precisely their limited opportunities to develop private interests that Plato in particular so admired.

Aristotle acknowledged that such forms of citizenship were only possible in small states. That was important not just so everyone could have a turn at ruling and to keep the tasks of government sufficiently simple as to be manageable without a professional bureaucracy or political class, but also because it was only in smaller settings that the requisite civic virtues were likely to be fostered. Although the Athenians probably invented the idea of taking a vote to settle disagreements, unanimity was the ideal and most issues were settled by consensus – if need be following extended debate. Aristotle surmised that such concord or *homonoia* depended on a form of civic friendship among citizens that was only likely in tightly knit communities. Citizens must know each other, share values, and have common interests. Only then will they be able to agree on what qualities are best for given offices and select the right people for them, harmoniously resolve disputed rights, and adopt collective policies unanimously. Even so, agreement rested on citizens possessing a sense of justice, being temperate by exercising self-control and avoiding extremes, having a capacity for prudent judgment, being motivated by patriotism, so they put the public good above private advantage, and being courageous before danger, especially military threats. In sum, a citizen must not belong 'just to himself' but also to 'the *polis*.'

Though the Greek model of citizenship model was the privilege of a minority, it provided a considerable degree of popular control over government. True, the Assembly and Council tended to be dominated by the high born and wealthy, while Aristotle's ideal of concord was often far from the reality, at least in Athens. There were persistent tensions between different classes and factions, with disagreements often bitter and personal, ending with the physical removal of opponents through ostracism and even their execution on trumped up charges of treason. Nonetheless, in a very real sense those people who qualified as citizens did rule, thereby giving us the word democracy from the Greek *demokratia* or people (*demos*) rule (*kratos*). Unsurprisingly, Greek citizenship has appeared to many later thinkers as the epitome of a true condition of political equality, in which citizens have equal political powers and so must treat each other with equal concern and respect. They have viewed the trend toward delegating political tasks to a professional class of politicians and public administrators with foreboding, as presaging a loss of political freedom and equality, and lamented the – in their opinion – short-sighted tendency for ever more citizens to desert public service to pursue personal concerns. By contrast, critics of this model of citizenship argue that it was not so much an ideal as hopelessly idealized. In reality, it was doubly oppressive. On the one hand, it rested on the oppression of slaves, women, and other noncitizens. On the other hand, it was oppressive of citizens in demanding they sacrifice their private interests to service of the state. As we saw, the two forms of oppression were linked: citizens could only dedicate themselves to public life because their private lives were serviced by others.

Later liberal commentators have condemned these last features of Greek republican citizenship as potentially despotic (Constant, 1988 [1819]; Berlin, 1969). They criticize not just the way noncitizens got treated as less than fully human, but also the demand for the total identification of citizens with the state, with all dissent seen as indicative of self-interest rather than an alternative point of view or valid concern. They castigate such regimes as both repressive and corrupt – not least in diverting all talent away from the private sphere of the economy on which the wealth of a society rests. Ironically, making the public sphere the main avenue of personal advancement did not prevent but promoted the abuse of power for private again. They trace these problems to a flawed view of liberty that falsely links freedom with civic participation. Aristotle's defense of this linkage rested on a perfectionist account of human flourishing, with civic involvement a means to human self-realization, whereby individual and collective autonomy can be reconciled by subsuming private interests under the public interest. Many liberals reject such 'positive' conceptions of liberty as suggesting human freedom lies in the pursuit of particular ends. Instead, they advocate a 'negative' conception that consists of being free from interference to pursue one's personal good in one's own way. They claim freedom of this latter sort merely requires a just constitutional regime that limits the power of government to maximizing freedom from mutual interference and has no intrinsic link with democracy.

Imperial Rome offers an important contrast in this respect and one that forms part of the genealogy of the liberal view. Eligibility for Roman citizenship was at first similar to the criteria for Greek citizenship – citizens had to be native free men who were the legitimate sons of other native free men. As Rome expanded – initially within Italy, then over the rest of Europe and finally into Africa and Asia – two important innovations came about. First, the populations of conquered territories were given a version of Roman citizenship while being allowed to retain their own forms of government, including whatever citizenship status they offered. Second, the version of Roman citizenship given was of a legal rather than a political kind – *civitas sine suffragio* or 'citizenship without the vote.' So, the Empire allowed dual citizenship, though it reduced Roman citizenship to a legal status. As a result, the legal and political communities pulled apart. The scope of law went beyond political borders and did not need to be coextensive with a given territorial unit. To cite the famous case of St Paul – on

arrest in Palestine, he proudly declared himself "a Jew of Tarsus, a city in Cilicia, a citizen of no mean city." But not being in Tarsus, it was his additional status as a Roman citizen that allowed him to claim rights against arbitrary punishment, thereby escaping a whipping, and to ask for trial in Rome.

According to the Aristotelian ideal, political citizenship had depended on being freed from the burdens of economic and social life – both in order to participate and to ensure that public rather than private interests were the object of concern. By contrast, legal citizenship has private interests and their protection at its heart. Within Roman law, legal status belonged to the owners of property and, by extension, their possessions. Since these included slaves, a free person was one who owned himself. So conceived, as in many respects it remains to this day, law was about how we could use ourselves and our things and those of others, and the use they may make of us and our things. As the example of St Paul shows, the resulting privileges and immunities, including the right to sue and be sued in given courts, were far from trivial. However, that the rule of law can be detached from the rule of persons, in that those subject to it do not have to be involved in either its making or its administration, creates disadvantages as well as advantages. The advantage is that the legal community can, as we saw, encompass a number of political communities and hold their rulers and officers to account, thereby limiting their discretion to act against the law. Law can be universal in scope and extent, enabling millions of dispersed individuals to pursue their private interests by engaging and exchanging with each other across space and, through such legal acts as bequests, through time, without any direct contact. The disadvantage lies in these same citizens becoming the imperial subjects of the law's empire, who are ruled by it rather than ruling themselves. Yet the rule of law is only ever rule through law by some person or persons. Law can have many sources and enforcers, and different laws and legal systems will apply to different groups of persons and have differing costs and benefits for each of them. If law's empire depends on an emperor, then the danger is that law becomes a means for imperial rule rather than rule of and for the public.

Toward Republicanism and Liberalism

Both these conceptions underwent significant alterations over time in response to changing social and political circumstances and new intellectual preoccupations. As a result, they gradually became reconfigured on rather different ontological and epistemological assumptions. Of particular importance were the struggles between religious and secular political authorities, on the one hand, and, crosscutting this conflict, those between city-states and monarchical rulers, including the imperial pretensions of successive Holy Roman Emperors, on the other. These struggles both shaped and were shaped by political thinking from the Middle Ages to the Reformation. Two related developments emerging from this process were particularly significant: the separation of religion and politics, and the crystallization of notions of political sovereignty – be it of the people or their rulers – in the context of a polity possessing the features of a state: namely, a monopoly of coercive power over those residing within its territorial boundaries. For example, each of them plays a key role in Marsilius of Padua's important tract *Defensor Pacis* (1324). This work draws on both the political and democratic and the legal and imperial conceptions of citizenship explored in the last section, adapting them to the context created by the two sets of struggles mentioned above to ground the legal sovereignty of the Emperor Louis of Bavaria against the claims of Pope John XXII in a doctrine of popular sovereignty.

It is against this background that we need to explore the significant reworkings of the two classic conceptions of citizenship brought about by Machiavelli and Hobbes, respectively. Both offer secular accounts of citizenship that link popular sovereignty to the right to rule of those possessing sovereign political authority. Yet its role within their respective accounts was very different. While Machiavelli appreciated the part laws can play in securing the rights and liberties of citizens under a monarchical regime, he contended liberty was only fully secured within a republic where the people exercised political power in ways that allowed them to mutually check each other, thereby obliging all citizens to act collaboratively and in the public good. By contrast, though Hobbes grounded the right to rule in the mutual consent of the people, he maintained that in the process the ruled surrendered their sovereign power to their rulers. Moreover, he regarded the unlimited and undivided sovereignty of an absolute ruler – preferably, though not necessarily, a monarch – as offering the surest basis for law and the protection of liberty.

Machiavelli's account draws on the Roman republican model of citizenship more than the Greek model associated with Aristotle, explored above. While there are some similarities between the two, there are also striking differences. Though classes existed in Greek society, including among those who qualified as citizens, the ideal of citizenship became classless with the aspiration to 'concord' a product of putting class and other private interests to one side. Instead, the Roman Republic was born of class discord and the struggle of the plebeians to obtain rights against the patricians. For the theorists of the Roman model – Cicero (1991 [44 BC]), the historians of the Roman republic and, drawing on them, Machiavelli (1970 [1531]) – this ongoing class conflict gave politics and citizenship a much more instrumental character than the Greek model theorized by Aristotle. Roman citizens never possessed anything like the political influence of their Athenian counterparts. Despite the creation of Tribunes of the People, elected by a Plebeian Council, true power rested with the Senate. While entry to the Senate ceased to depend on rank around 400 BC, since it was composed instead of the popularly elected magistrates, it was dominated by the patricians – especially among the higher magistracy, particularly the Consuls who formed the executive. The slogan *Senatus Populusque Romanus* ('The Senate and the Roman People,' frequently abbreviated to SPQR) suggested a partnership between the Senate and the people within the popular assemblies. In reality, Senate and people were always in tension, with the influence of the plebeians waxing and waning depending on their importance as support for different factions among the patricians.

Applying these ideas to Renaissance Florence, Machiavelli argued the Roman experience showed how the selfish interests of the aristocracy and the people could only be restrained if each could counter the other. The republic institutionalized such mutual restraint by ensuring no person or institution

could exercise power except in combination with at least one other person or institution, so each could check and balance the other. The need to divide power in this way was elaborated by later republican theorists. It was a key feature of the city-states of Renaissance Italy, especially Florence and Venice, which inspired Machiavelli's writings on the subject, and influenced the political arrangements of the Dutch Republic into the eighteenth century. Republican ideas also informed the constitutional debates of the English Civil War of the seventeenth century, influencing writers such as Milton and Harrington. In the work of Montesquieu and, following him, the American *Federalists*, especially Madison, the check and balance of powers became a central element of the US Constitution (Hamilton et al., 2003 [1787–1788]).

Underlying this account was a distinctively realist view of citizenship, which could be more easily adapted to modern democratic politics than the Greek view. Instead of viewing the private interest and the public interest as diametrically opposed, so that all elements of the first had to be removed from politics, the public interest emerged from the clash and balancing of private interests. Consequently, citizens had self-interested reasons to participate because they could only ensure that their concerns figured in any collective decisions so long as they took part and were counted. Quentin Skinner (1998) and Philip Pettit (1997) have argued that the neo-Roman version of republicanism rejects the 'positive,' Aristotelian view of liberty as self-mastery for a 'negative' account of freedom as the absence of domination or mastery by another. Citizens need not identify their will with that of the polity; merely seek to ensure that government and the laws address the interests of all in an equitable manner through being obliged to 'hear the other side.' Liberty results from a political system where none are the masters of others because all have an equal influence over how public policies are framed and implemented.

Once again, this republican argument can be contrasted with the liberal notion of liberty as freedom from interference. As we noted, this position has its origins in the Imperial view of citizenship centered on providing the legal protection of an individual's civil liberties, especially the right to property. Much as Machiavelli can be regarded as defending the link between political citizenship and liberty on a new basis, Hobbes can be read as criticizing this linkage and putting forward a new defense of the link between legal citizenship and liberty. In framing his argument, Hobbes drew on the contemporary natural law tradition in which individuals are conceived as proprietors of themselves and the world, possessing rights in both for their self-preservation. Although Hobbes regarded humans as capable of perceiving and pursuing laws of nature, he did not believe these precepts allowed them to live peacefully without government. Infamously, he depicted the state of nature as a war of all against all. He ascribed this condition to each person being judge, jury, and executioner in their own case and acting on their own private judgment – itself a product of their exercising their 'right of nature' to do anything which they judged necessary to their preservation. As a result, in the natural state people would live in a permanent condition of insecurity in which neither industry nor any of the activities associated with civilization would be possible. Hobbes contended each person ought to be rational enough to see this state was not conducive to their ability to safely pursue their interests safely and to perform those actions most conducive to peace – a set of practical imperatives he terms the Laws of Nature. The solution was for individuals to lay down a part of their right to all things and to establish an absolute sovereign with sufficient power to hold all in awe. Hobbes contended the passage from the natural to the civil state could be regarded as the product of a mutual covenant or social contract between the members of society, whereby they ceded their right to private judgment concerning those matters most conducive to their preservation to a sovereign political authority. So long as these sovereign authorities could offer effective protection to those subject to their rule, the ruled had an obligation to obey their commands. Nevertheless, the ruled retain a right to self-defense that allows them to resist a sovereign that puts their lives in danger.

Hobbes sketched much of this argument in a book published in Latin in 1642 with the title *De Cive*, or 'On the Citizen,' although it got its most famous statement in the English version of the *Leviathan* published in 1651. From the republican perspective, his argument that citizenship was secured through subjection to an absolute Leviathan seems like a contradiction in terms. However, Hobbes takes issue with this view. Writing in the context of the English Civil War and the religious conflicts of contemporary Europe, Hobbes contended that sovereignty cannot be divided or limited and still offers a reliable source of stability and peace. To divide or seek to limit sovereignty is to risk institutionalizing the disagreements and conflicts that characterize the state of nature and would undermine the effectiveness of the sovereign's authority. Moreover, the citizens of a despotic regime could enjoy as much liberty as, and possibly even more than, those of a self-governing republic, since they too could live under the protection of laws that guaranteed their ability to exercise their rights in pursuit of their private interests.

Both Hobbes' view of the state of nature and his claim that sovereignty must be absolute were disputed by others writing in this tradition. For example, John Locke (1988 [1690]) thought that human nature was more benign than Hobbes and believed he had underestimated the degree to which state power might be an even greater danger to an individual's liberty than other individuals. Nevertheless, the contrast with the republican account of citizenship persists. Two features are especially important. First, rights are commodified as individual possessions, with political society being justified by providing for their preservation. Rights are subjective, pre-social, and prepolitical rather than being grounded in what is objectively or politically determined as right or good for a society, as the Greek and neo-Roman notions contended. Second, political legitimacy rests on a presumed act of consent whereby sovereignty is transferred from the people to the political institutions that govern them. The presumption of consent rests on the supposed rationality and necessity of this transfer once individuals begin to interact with each other on a regular basis. It is then held to persist until such time as the relevant institutions or persons fail to maintain the terms of the original compact, with the continued political participation of citizens an optional extra.

This mode of argument has proved tremendously influential in international law, especially human rights law (Pufendorf, 1991 [1673]; Kant, 1970 [1795]), and fed into

contemporary cosmopolitan conceptions of citizenship. A natural affinity also exists between this account and the liberal defense of the constitutional state. The state and its authorities are deemed to be bound by the act of constitution that justifies and legitimizes their institution, which thereby serves as a higher law to which they can be held to account – ultimately by the people, but in some accounts by their authorized representatives too – be they judges or politicians. This position also fed into views of commerce as resting on a natural system of liberty grounded in the natural rights to ownership of oneself and one's possessions.

Significantly, all three come in for trenchant criticism from J.J. Rousseau (1985 [1755], 1968 [1762]), who subjects the natural law tradition to a radical republican critique and reworking. Rousseau contends that the state of nature only takes on a Hobbesian character once individuals interact and become mutually dependent on each other, yet he agrees with Hobbes that to the extent that states are in this condition in the international sphere they too are in a state of war. However, he regards the Hobbesian social contract as systematically disadvantaging the propertyless and exploited, who only accept it out of fear. His solution was to propose a republican social contract in which the natural freedom each individual enjoyed when independent from others in the state of nature is replaced by a civil freedom that derives from each citizen participating directly in formulating laws that accord with a general will that stems from and applies equally to all. In other words, as with Hobbes sovereignty is single and indivisible, but it remains popular as only then will the laws favor the common interest rather than the partial interests of certain particular individuals over others. The difficulty was that Rousseau doubted that citizens would consistently will what was generally for the good of all – that perhaps such collective goods would not exist – outside of relatively small, undifferentiated political communities of moderate wealth. On his reading of republicanism, therefore, the original dilemma apparently persists whereby a society of equal citizens who rule and are ruled in turn only seems possible in societies that are exclusive in their membership and constrain the private lives of citizens – a vision that seems both anachronistic and coercive. As Adam Smith (1976 [1776]) and Benjamin Constant (1988 [1819]), two of Rousseau's prominent critics, noted, allowing each citizen to pursue their private interests so far as was compatible with a like pursuit by others might result in social and economic inequality but it also fostered both the commerce necessary for the wealth of nations and provided greater opportunities for individuals to exercise their liberty. Yet, both retained republican worries that in a society depleted of civic virtue, the necessary, if minimalist, state regulation risked being exploited by the rich and powerful for their own ends, and Smith especially was concerned for the misery of the poor. Therefore, a central issue was whether a modern commercial republic was possible.

Liberal Democratic Citizenship: Uniting Republican and Legal Citizenship?

The opportunity to create a modern republic confronted the two great revolutions that inaugurated the modern democratic era – the American Revolution of 1776 and the French Revolution of 1789. Both attempted to resolve it by seeing their constitutional settlements as instances of an actual contract between citizens. So, the putative authors of the American Constitution are 'We the People of the United States,' while the French Declaration of the Rights of Man and the Citizen declares "the source of all sovereignty lies essentially in the Nation." However, these formulas preserve a dualism between the 'public' political citizen, who acts as a collective agent – the 'people' or the 'nation' – and the private, 'legal' citizen, who is the subject of the law and the possessor of 'natural' rights to liberty, property, and the pursuit of happiness. Civic virtue gets assigned to a single constitutional moment and enshrined in the institutions that popular act creates, leaving selfish citizens to pursue their personal interests under the law. Meanwhile, a tension between the two models persisted. As Rousseau had noted, it is doubtful that even the most well-designed institutions and laws can economize too much on the virtues of citizens, or that citizens feel they are 'theirs,' if – the founding moment apart – they cannot actively participate in shaping them.

The liberal democratic regimes that emerged during the nineteenth and twentieth centuries struggled with this tension, mixing in their different ways the elements of both the republican and the legal forms of citizenship. Lying midway between a city-state and an empire, the nation-state emerged as their most viable alternative – able to combine certain key advantages while avoiding their disadvantages. If the *polis* was too small to survive the military encroachments of empires, the Empire was too large to allow for meaningful political participation. The nation-state had sufficient size to sustain both a complex economic infrastructure and an army, while being not so large to make a credible – if less participatory – form of democracy impossible. As a result, it became subject to pressures to create a form of citizenship that could successfully integrate popular and legal rule by linking political participation and rights with membership of a national democratic political community.

The sociologists T.H. Marshall (1950) and Stein Rokkan (1974) established what has become the standard narrative of the evolution of modern democratic citizenship. They saw citizenship as the product of the interrelated processes of state building, the emergence of commercial and industrial society, and the construction of a national consciousness, with all three driven forward in various ways by class struggle and war. The net effect of these three processes was to create a 'people,' who were entitled to be treated as equals before the law and possessed equal rights to buy and sell goods, services, and labor; whose interests were overseen by a sovereign political authority; and who shared a national identity that shaped their allegiance to each other and to their state. In a brilliant essay, Marshall argued there had been three periods in the historical evolution of citizenship as a given group fought to attain equal status as a full member of the community. The first period, from the seventeenth to mid-nineteenth centuries, saw the consolidation of the civil rights needed to engage in a range of social and economic activities, from the freedoms to own property and exchange goods, to liberty of thought and conscience. The second period, from the end of the eighteenth century to the start of the twentieth, coincided with the gaining

of political rights to vote and stand for election. The third period, from the end of the nineteenth to the midtwentieth, involved the creation of social rights that gave citizens "the right to share to the full in the social heritage and to live the life of a civilized being according to the standards prevailing in society."

Though modeled on Britain, Marshall's account reflects not just the new liberal and social democratic consensus behind a welfare state fashioned by such British thinkers as T.H. Green, L.T. Hobhouse, and W.H. Beveridge, but also similar intellectual and political movements elsewhere, like the Solidarists in France and progressives in the United States (Bellamy, 1992; Kloppenberg, 1986). Nevertheless, his argument has attracted considerable criticism. He is said to overlook the role external pressures played in promoting rights (Mann, 1987), while the three sets of rights neither arose in quite the order or periods that he mentions, nor proved quite as complementary as he assumed. Thus, social rights emerged in most countries before rather than after political rights – often being offered by the politically dominant class in the hope of damping down demands for political rights. Social and civil rights can also clash, as with the right to property (Bellamy et al., 2004). However, these corrections to the details of his argument are perfectly compatible with its underlying logic, whereby the development of legal rights stems from a subordinate group employing formal and informal political strategies to win concessions from those with power in their fight to be treated with equal concern and respect.

Writing in the 1950s, when the economies of west European countries were in the ascendant and welfare spending expanding, it was natural for Marshall to view social rights as the culmination of the struggle for an ever more inclusive and egalitarian form of citizenship. Needless to say, subsequent events have tended to challenge that optimistic conclusion. For a start, many aspects of the postwar welfare settlements Marshall celebrated got eroded during the economic downturn and restructuring of the 1970s, 1980s, and 1990s. Various New Right politicians and theorists argued for the privatization of numerous public services on the grounds they would be not only cheaper and more efficiently run but also more responsive to consumer pressure via a free market than they had been to the democratic pressures of voters upon politicians and state administrators. They also questioned whether welfare was a right of citizenship (King and Waldron, 1988). Many of the economic and social assumptions on which this settlement rested have also been criticized by those seeking to further expand rather than curtail citizenship. Environmentalists have attacked the emphasis on increasing economic production (Dobson, 2003), feminists its continued overlooking of the subordinate role of women (Lister, 2003), multiculturalists the failure to even mention issues of cultural, religious, or ethnic diversity (Kymlicka, 1995), cosmopolitans its focus on the nation-state (Benhabib, 2004), and so on.

These developments have challenged the view of the sovereign, liberal democratic, nation-state as the context for citizenship. Internally, it has been argued that the people have become too diverse for popular sovereignty not to risk degenerating into the tyranny of the majority unless minority rights have strong legal protection. Externally, state sovereignty has been regarded as both ineffective and unjust. Ineffective, because the state cannot offer citizens economic or physical security in a world dominated by global markets and global threats such as climate change, international terrorism, and nuclear weapons. Unjust, because birth into a rich or a poor, a democratic or a tyrannical state is simply a matter of good or bad luck. State sovereignty merely allows citizens of rich and democratic states to avoid their duties toward the citizens of poor and tyrannous states, often adding to their poverty and tyranny in the process. Yet, if the new forms of multinational and global citizenship attempt to go beyond sovereignty, they have for the most part found inspiration in the presovereign, classical models of ancient Greece and Imperial Rome and remain caught in the dilemma of reconciling the advantages and avoiding the disadvantages of the republican and the liberal, the democratic, and the legal models of citizenship.

Abstract

Citizenship is an inherently political status conferring the right to self-governance. Yet recurrent emphasis upon its legal, social, and psychological aspects, often by political actors themselves, creates pressure to depoliticize citizenship. Even when its core of self-rule is obscured, the theory and practice of citizenship follow and respond to political power. Participatory (or republican) and legalistic conceptions of citizenship stand in particular tension but are logically and practically bound together, both in modern national citizenship and in the nascent politics of transnational membership.

It may seem superfluous to subtitle a discussion of citizenship as 'political.' The term is at core ineradicably political: its oldest, most basic, and most prevalent meaning is a certain sort of membership in a political community. There are, nonetheless, good reasons to underline just how deeply political citizenship is. The chief reason is that precisely because citizenship is so profoundly political a term, there are recurrent pressures to depoliticize both its meaning and its accompanying practice. These pressures and the understandings of citizenship they propagate, are best seen as confirmations of the political character of citizenship, not as alternative, apolitical conceptions.

Five Meanings of Citizenship

(1) Perhaps the most familiar meaning of citizenship is, in fact, the seminal one. In both ancient and modern republics and democracies, a citizen has been a person with political rights to participate in processes of popular self-governance. (2) Yet we also commonly speak of citizenship as a more purely legal status. Citizens are people who are recognized legally as members of a particular political community and who, therefore, possess some basic rights to be protected by that community's government, whether or not those rights include rights of political participation. (3) During the last century, many have come to use the term 'citizen' as a way of referring to those who belong to almost any human association. I can be said, metaphorically, to be a citizen of my neighborhood, my fitness club, and my university as well as my broader political community. (4) Two subsidiary uses denote aspects of citizenship that pertain to all of the first three meanings. Citizenship can refer to the collective identity uniting the members of a given association, whether a political community or some other group. The value of such a social identity is a large part of what makes citizenship a central political good. (5) Finally, we often use citizenship to signify, not just membership, but certain standards of proper conduct, implying that only 'good' citizens are truly citizens in the full meaning of the term.

Which of these meanings of citizenship can we properly term 'political'? If we understand politics simply as the distribution and use of power, all three of the initial meanings are political. We commonly speak of 'office politics' just as we speak of the 'politics of labor rights,' or the 'politics of governance' which are politics proper. The three meanings are not political in the same degree, however, and they are listed roughly in descending order. The first meaning makes the citizen both the agent and the beneficiary of public power. Ongoing collective action is at the core of this meaning. The second meaning sees the citizen mainly as the beneficiary of political power. The rights and duties of citizenship here are established by authoritative decision, but the status need not have any further connection to politics. In contrast to the first two, the third meaning involves the citizen in associations that lack final coercive power, but which, nonetheless, may involve structures of authority over goods, rights, and duties. The citizen in this third sense may be agent or beneficiary, depending on the nature of the association; but the power in question is not characteristically political. The same basic ranking holds under a refined conception of a political relationship – either in its ancient sense requiring the exchange of reasons between ruler and ruled or in the classical modern sense of mutual subjection to a common authority. Citizenship as norm and collective identity will concern the use of power to the extent that they correspond to one of the three primary meanings of citizenship.

The word citizen derives from the Latin *civis*, meaning a member of an ancient city-state, preeminently the Roman republic; but *civis* was a Latin rendering of the Greek term *polites*, a member of a Greek *polis*. Innumerable scholars have told how a renowned resident of the Athenian *polis*, Aristotle, defined a *polites* or citizen as someone who rules and is ruled in turn, making citizenship conceptually inseparable from political governance (Aristotle, 1968: p. 1275a23). Aristotle doubtless pleased many Athenians by arguing that such a status and activity, properly performed, represented the highest form of life available to most people. Yet this life was not available to Aristotle himself; he was not an Athenian citizen but a metic, a resident alien. He also suggested that the philosophic life he could and did pursue was, in the end, the highest of all; and the fact that he chose to pursue this life in a city that denied him citizenship may call into question how valuable he really thought citizenship to be.

His fulsome praise of the citizenship his Athenian hosts had created thus suggests how greatly definitions of citizenship have always been shaped by the political structures of power within which they have been offered. It clearly would not have been prudent for Aristotle to denigrate Athenian citizenship. The fact that neither Aristotle nor most of other residents of Athens – including aliens, women, and slaves, – were eligible for citizenship also underlines how citizenship originated; not only as a way of structuring membership but also as a way of distributing power within a particular political regime. That distribution disempowered many more Athenians than it enfranchised. Even so, the ideal of citizenship as self-governance that Athens and Aristotle established, has often served since as an inspiration and instrument for political efforts to achieve greater inclusion and engagement in political life.

As such, this ancient idea of citizenship has often seemed politically threatening to many rulers, who have abolished or redefined the category. It was for this sort of political reason – because the regimes that had created citizenship succumbed to conquest by Alexander the Great's monarchical empire – that ancient Greek citizenship disappeared. And it was for a similar political reason – because the Roman republic gave way to imperial rule generated from within – that Roman citizenship came to have a different meaning than the one Aristotle articulated. In principle, Roman citizenship always carried with it the right to sit in the popular legislative assembly that had been the hallmark of Athenian citizenship. But as participation in that assembly became increasingly meaningless and impractical for most imperial inhabitants, Roman citizenship became essentially a legal status comparable to modern nationality (Pocock, 1995). It provided rights to legal protection by Roman soldiers and judges in return for allegiance to Rome. That status was less 'political' in the sense that it no longer evoked recurrent engagement in practices of self-governance, but it was quite plainly a politically crafted status that represented a new distribution of power of enormous political significance.

Citizenship was then eclipsed in the West by the various feudal and religious statuses of the medieval Christian world, where no community could claim the exclusive allegiance of its members. The claims of what would later develop into sovereign nation-states, were limited from below by the personal authority of local rulers and from above by the universal claims of the Christian church. Yet citizenship did not vanish entirely. 'Burghers,' or the *bourgeoisie*, were citizens of municipalities that often had some special, if restricted, rights of self-governance within feudal hierarchies. Such burghers remained, however, fundamentally subjects of some ruling prince or lord, with their citizenship chiefly providing legal rights of protection in the manner of Roman imperial citizenship. In contrast, during the Renaissance, some Italian cities achieved both independence and a meaningful measure of popular self-governance. They invoked the ancient 'republican' ideals of participatory citizenship to define and defend their regimes. Their experiences, in turn, fed into the antimonarchical revolutions that created the first modern republics, including the short-lived, seventeenth-century English Commonwealth and the late eighteenth-century French Republic, as well as the still-enduring United States (Pocock, 1975).

In complex fashion, those revolutions inaugurated transformations 'from subjectship to citizenship' across much of the globe that are still ongoing. Today most of the world's governments proclaim themselves to be 'republics' of some sort populated by citizens – whether or not their political practices correspond to any historical meanings of these terms. With its political use greatly broadened, the term 'citizen' has been further extended to cover almost every kind of membership in any organization and to equate genuine citizenship with being a good, contributing member of those organizations. These pervasive popularizations of the term reflect, however, political developments that have in some respects diminished the significance of citizenship, even as the term has spread.

The Politics of Apolitical Citizenship

The early modern republics were formed in an international realm that had been organized by the 1648 Treaty of Westphalia into a system of mutual recognition among overwhelmingly monarchical nation-states. In gaining acceptance within that system, the new republics defined their citizens as having the same international status as national monarchical subjects. For international purposes, these citizens, too, were simply persons who owed allegiance to, and could claim protection from particular governments. Thus, Westphalian international law treated modern republican citizenship as akin to the legalistic, protection-oriented version of Roman citizenship.

Americans, especially, forged their republic amid racial and gender hierarchies that few leaders sought to challenge. Hence they felt compelled to argue that though free blacks and women might be citizens, citizenship did not, in fact, inherently entail rights of political participation. It guaranteed, once again, only more limited rights to certain judicial and executive protections (Smith, 1997). For long stretches of time, then, both international and domestic politics worked to strengthen legalistic, as opposed to the more participatory conceptions of citizenship, despite the rise of modern republicanism.

Even though courts made the narrower, protection-centered view of citizenship legally authoritative, the notion that genuine citizenship involved rights of political participation remained a resonant rhetorical tool of legislative and constitutional reformers. Eventually both domestic protest movements and international pressures, including the need for broad support in wartime, converged to work for the expansion of the franchise to all adult citizens in the United States and most of the Western world. In America, blacks won both citizenship and voting rights after the Civil War, even though most came to be effectively disfranchised in the 'Jim Crow' segregation era; and women gained the franchise after World War I. In both cases, arguments emphasizing the public service of the disfranchised, especially in wartime, and the idea that true citizenship must include the franchise, played key roles in their enfranchisement (Foner, 1988; Flexner, 1973). In Britain, and to some degree in other Western European nations that had been politically configured essentially by feudal and industrial class systems, modern citizenship was wrought out via somewhat different struggles. As Marshall famously argued, first middle class and then working class political pressures resulted

in the expansion of the civil rights of property and protection, then in near-universal rights of political participation, and finally and incompletely, in 'social rights' for all national citizens, which included income, housing, medical, and educational guarantees (Marshall, 1950).

But even as the franchise has broadened in the United States, Europe, and elsewhere, the notion of citizenship as active participation in meaningful self-governance has become more remote to many modern citizens. In part, the logistics of large-scale modern societies make effective democratic participation very difficult. In part, the economic and cultural developments that have led to a focus on 'social citizenship,' make political activism seem less important. Engagement in social and economic organizations can appear more pressing and efficacious. Succeeding postwar generations increasingly favor direct action on issues such as global poverty and the environment, bypassing traditional political questions and modes (Dalton, 2009). Perhaps, then, the term citizenship has become common in such contexts because it is there that people find the active social memberships that remain at the heart of the concept of citizenship (Carens, 2013). If so, then the inevitable corollary is that citizenship, understood as political self-governance, has become quite secondary to many modern citizens. Yet this, too, is a signal political development. It is probable that like their predecessors in other regimes, many who wield power in modern republics are content when those they govern think of citizenship chiefly in terms of subnational, often nongovernmental associations; and in terms of the 'good citizen's' civic service rather than vigorous political participation. Certainly few policies within modern republics do much to enhance the feasibility and potency of such participation.

By their very logics, citizenship as self-governance and citizenship as legal status are driven apart and also drawn back together. The history of citizenship has borne out this dual motion. Popular self-governance, famously termed "the liberty of the ancients," does not easily accept limitation by personal legal immunities, "the liberty of the moderns" (Constant, 1988). Neither do these two aspects of citizenship flourish in the same conditions. As citizenship expands to include more members, a genuinely consequential form of self-rule grows less feasible. Each citizen's share of decision diminishes as the citizenry grows. Changing institutional forms, from direct to representative forms of governance, can maintain formal participation but not real influence for citizens of large communities. While citizenship as meaningful self-rule, the 'Greek' form, cannot be indefinitely expanded, legalistic citizenship can extend as far as a polity can project bureaucratic and judicial power. This 'Roman' variant of citizenship not only permits, but even encourages a larger communal setting. As James Madison famously argued, in a large republic, the smaller share of power possessed by discrete members will hamper the use of politics to violate others' rights (Madison, 2001). Participatory and legalistic citizenship are set in tension by the divergent conditions that favor the one or the other.

A different logic explains why the several meanings of citizenship have not broken apart into separate concepts. Legalistic citizenship emphasizes the rights and duties that legal status brings. Yet that status is defined and implemented by political action. Citizenship that does not involve self-rule, i.e., participation in the politics that undergirds the status itself, is precarious. It depends upon the good offices of those exercising political power to maintain its character. There is thus a powerful incentive to insist upon participation as a guarantee of political, social, or civic benefits. This logic underwrote the modern extension of the franchise. Conversely, the practice of political, and especially democratic participation conduces the establishment of legal immunities like those at the heart of modern citizenship (Ober, 2005). The practical connection between the two dominant meanings of citizenship binds them together and helps to explain the continuing appeal of citizenship as self-rule, even in an institutionally inhospitable setting. Although modern citizenship renders participatory self-governance difficult, we should not expect this dimension of citizenship simply to evaporate.

The Prospect of Postnational Citizenships

Though some activists and scholars lament decreasing participation in national politics, others stress that the heightened transnational economic, transportation, and communication systems that we call globalization are in any case making traditional notions of national citizenship obsolete. Regional associations, international legal institutions, and transnational economic, cultural, and political organizations are all said to be more likely to shape humanity's future than existing national regimes. Hence membership in such bodies may represent the most important forms of citizenship in the twenty-first century (Bauböck, 1994). What these changes will entail for a political form of citizenship is as yet unclear, because several avenues are possible.

The postwar rise of human rights ranks among the most important developments for the theory and practice of modern citizenship, with its emphasis on legal status. Many of the benefits once accorded on the basis of shared nationality are increasingly anchored in universal humanity. Such benefits include not only rights against harm, but also positive legal powers and even social entitlements, e.g. to education or health care. As the slate of benefits accorded to all persons expands, the relative worth of national citizenship diminishes. "The logic of personhood supersedes the logic of national citizenship" (Soysal, 1994: p. 164). Formal political rights are not typically granted to noncitizens, but universal rights regimes secure many of the substantive benefits that once made political rights desirable. Global conventions on human rights and the institutions that enforce them, might thus be said to form the basis of a cosmopolitan citizenship. Such a view emphasizes citizenship in its legalistic sense, since the prospect of a global collective identity, much less broad participation in geopolitical institutions, remains remote. Some thinkers, wary of the global scope of this trend, have proposed *ius nexi* (Shachar, 2009), whereby the benefits of citizenship are granted on the basis of social membership in a polity rather than legal status. In both cases, the denationalization of rights already challenges the exclusivity of national citizenship but broader globalizing trends may reconfigure the meanings of citizenship in any of three ways.

First, citizenship may retain the political aspect of self-governance along with legal protections, but in the context of enlarged or redrawn political communities (see Isin and Saward, 2013). This is likely to the extent that "multinational politics" becomes a practical reality for individuals. Increasingly, personal activities and important human goods involve interactions with cross-national groups such as large companies or NGOs, and with international bodies such as the European Union or the United Nations. Citizenship in the sense of self-rule is possible in such groups largely to the extent that individuals participate in, and are governed by them in direct fashion. On the other side, inasmuch as national governmental actors remain major players in transnational organizations, the individuals' relations to such groups constitute a dimension of national citizenship rather than a separate locus of membership. But if power and legitimacy transfer to transnational bodies, rendering them self-governing political communities in a real sense, participatory self-rule can and indeed must concern collective action at this level. Citizenship in transnational communities would likely be legalistic to at least the same degree as modern national citizenship, due to their large scale (although the population of the whole European Union, for instance, is far smaller than that of the most populous states). To the extent that transnational communities become genuinely self-governing, thus encroaching upon the sovereignty of nation-states, citizenship could attach to them and retain its political character.

Second, globalizing trends could also foster a depoliticized 'world citizenship' if claims of membership run ahead of actual contexts of power, legitimacy, and shared meanings. Changing norms of 'engaged citizenship' (Dalton, 2009) point beyond the national political context to issues of global poverty, climate change, and international social justice. Such citizenship is understood as membership in an imagined world community facing these global issues (Cabrera, 2010). Cosmopolitan projects do not belong to political self-rule, however, if they are undertaken in the hope of collective action but lack any structures of authority, reciprocity, or mutual knowledge (see Miller, 2000). Those who merely share a global ethic are not yet fellow citizens. Yet suppose that a durable shift in the norms of good citizenship did take place along these lines, effectively depoliticizing citizenship by putting it out of phase with political reality. One would expect, nonetheless, that a normative shift toward cosmopolitanism would be followed by a corresponding shift in the legal form of citizenship, and ultimately, by some reinvigoration of political participation in the newly imagined and instituted community. The several meanings of citizenship, while distinct, are mutually influential and unlikely to diverge completely. The normative sense of citizenship exerts some pull on its legal and political meaning. On the one hand, then, ideas of global citizenship may be drained of political content if they posit membership in a community that neither exists nor governs as a matter of real human interaction. On the other hand, cosmopolitan norms can themselves serve as reasons to enact the envisioned reality, drawing citizenship and politics together.

Third and finally, globalizing trends that make the nation less salient also open the possibility of local (or subnational) forms of citizenship. If transnational bodies do come to a larger, genuinely political role, they may offer only slight prospects for participation and collective identity. If so, the value of direct participation that historically inhered in the notion of citizenship may favor the reinvigoration of local forms of membership and self-rule (Maas, 2013). The scale and impersonality of national citizenship already encourage private forms of collective action. A global citizenship of human rights would only sharpen this movement. It is possible that organizations formed for localized civic service (more than global activism) might consolidate genuinely political functions and so provide the chance for self-governance that legal citizenship in a far-flung community does not. Local forms of citizenship could offer stronger collective identities by differentiating from other groups (Benhabib, 1996), than a universal citizenship offering no communal distinctness. This possibility envisions currently subpolitical groups taking on genuinely self-governing roles and so becoming political. In this scenario, the participatory and legal aspects of citizenship would diverge in large degree, with rights anchored in large communities and self-rule attached to small ones. This divergence would render the arrangement less stable in the long term, because of the logical and practical forces binding the aspects of citizenship together.

The prospects of postnational membership are various, and it is unclear how far national citizenship will recede in the face of globalization. History suggests that the leaders of political communities rarely give up power willingly, either to encompassing or to constituent groups. It is not surprising that efforts to resist globalizing trends and reinvigorate loyalties to existing nations and regimes are also visible in modern 'citizenship politics,' particularly in regard to immigration policies. None of the avenues for postnational membership, moreover, envision the disappearance of national citizenship – only its dilution by competing communities of identity and self-rule. Citizenship will likely track the foci of political power as they shift or fragment, and so the fate of national citizenship will be bound up with the sovereign state. But whatever forms of citizenship result, they will almost certainly be the products of political contests that result in distributions of powers and memberships to some people and not others, – distributions that will convey to them certain rights and protections, and not to others. Hence, citizenship will remain what it has always been, a fundamentally political status through which human beings partly order both their individual and their collective lives.

This article is a revision of the previous article by P. Birnbaum, volume 3, pp. 1860–1862, © 2001, Elsevier Ltd.

Abstract

This article defines citizenship and discusses its three basic theoretical traditions. We then delve into seven important areas of citizenship in terms of how: (1) rights and obligations have grown, (2) identities are framed for new citizens; (3) citizenship is universal or particular, or individual or group-based; (4) citizenship is contained within boundaries and externalized to the global; (5) citizenship is structured into various regime types; (6) citizenship has moved from being a status to involving people in a process; and (7) citizenship may develop in the future with new technologies.

In sociological theory, citizenship is defined as the active and passive membership of individuals in a rights-giving and obligations-receiving entity – such as a nation-state, the European Union, and even the world – where specified universalistic rights and obligations approximate a certain level of equality. This definition builds upon the foundation laid by Thomas H. Marshall (1964), who put forward the sociological concept of citizenship as a progression of legal, political, and social rights, framed within a context of the British welfare state of the 1950s. His theoretical framework was largely based on Tocqueville and Durkheim's conceptions of society, and despite his attention to class conflict, many attribute his developmental theory of rights to functionalist influences.

Two decades later, Brian Turner (1986) advanced citizenship theory to explicitly include conflict perspectives that emphasized the role of identity-based social movements aimed at expanding notions of personhood for excluded groups (race, gender, and class) and extending existing or new rights to nascent groups. More recent investigations propose an orientation that seeks to balance the development of rights with obligations at the individual and group levels of society (Janoski, 1998), or seeks to deconstruct citizenship into more particularistic rights for different groups (Lister, 2010). An emerging element in this progression of theory formation is the conceptualization of citizenship in new or developing nation-states.

The sociological discipline offers a broad range of theories that analyze citizenship in diverse relational contexts that are governed by identity and power. Political and liberal theoretical orientations are concerned with individualized rights, property, and voting. They emphasize rights over obligations (Rawls, 1971, 1993). Social democratic or deliberational theories focus on the citizenry, and debate how alternatives will persuade and then benefit the many (Habermas, 1989, 1996). These approaches tend to offer a more balanced view of rights and obligations. Communitarian theories are more concerned with the well-being of communities, and they emphasize obligations more than rights (Etzioni, 1993; Kymlicka, 1995). Postmodern and related theories have argued against essentializing citizenship. They withdraw concepts of universality in favor of emphasizing value change or deconstructing citizenship as a very particular set of rights and obligations for specific groups to pursue (Inglehart, 1997; Bauman, 2007). Some multiculturalists have argued that legal citizenship status doesn't matter since many immigrants and minorities can access all the rights of other citizens; and they suggest that dual nationality seems to be rampant and undermines the construct of citizenship. However, recent events have shown that these rights can be taken away, and naturalization examinations in various European countries ask for some rather specific cultural information (e.g., how to react to having beer spilled on you in a pub in the UK, or having to watch films showing a wide variety of sexual orientations in the Netherlands). So what was once thought to be totally multicultural is looking more like assimilationist socialization. For a review of these theories, see Janoski (1998) and the 'approaches' chapters in Isin and Turner (2002).

Viewed collectively, sociological theories tend to emphasize social and politico-economic aspects of citizenship over and above the legal. In particular, the focus is on: (1) the expansion of rights and obligations; (2) framing the identities of new, existing, or disqualified persons; (3) universal versus particular and individual versus group citizenship; (4) internal versus the external boundaries of citizenship; (5) citizenship variations across regime types; (6) citizenship as a process; and (7) citizenship in the future in the light of emerging technologies. We review these topics in more detail in the rest of this article.

Expanding Rights and Obligations

Numerous books and articles have been written about the development of rights over time across countries. Many of these studies were not necessarily about citizenship, but covered topics about workers forming labor unions, women fighting for freedom of choice, racial groups demonstrating in the civil rights movement, ethnic groups battling for recognition in immigration laws, and so on. In the 1970s, citizenship gained currency and more people working on these different issues espoused a citizenship-focused theoretical framework. This increased interest in citizenship was symbolized by Evelyn Nagano Glenn when she adopted 'citizenship' as the topical theme of her presidential convention for the American Sociological Association (2011). A bit less common are studies that follow the development of the four various kinds

of citizenship rights – legal, political, social, and participation rights. A study that puts the legal and political rights history of the US together over a long period of time is Rogers Smith's *Civic Ideals* (1997). The welfare state literature in political sociology has done extensive work on the development of citizenship rights over time, especially with time-series and pooled analyses of the advanced industrialized countries.

Scholars from western liberal countries, with a few exceptions, tend to ignore or minimize the obligations associated with citizenship, and focus more on rights. Generally, it is the conservative scholars who look at the long-term development of obligations, such as taxing policies, military conscription, jury duty, and so forth. Following the lead of Alexis de Tocqueville, other sociologists study the roots of volunteering, civic engagement, and political participation in relation to the development of citizenship (Musick and Wilson, 2008). Political sociologists also focus on political engagement in the form of campaign contributions, working on campaigns, and running for office as a form of citizenship behavior particular to democratic contexts. While criminology emphasizes the study of obedience to the law, sociology tends toward studying opposition to the law, especially in the form of social movements. In this manner, a sociological perspective is distinct because it underscores the importance of equally understanding rights and obligations in the process of citizenship.

New and/or Disqualified Persons

Personhood – the status of being a citizen – is controversially tied into social and political conceptualizations of citizenships. Acknowledgment of personhood is frequently used in the process whereby an individual from an excluded group gains a status as a citizen. The disqualified are denied personhood because of perceived or real deficiencies in reason, morals, or divergent national or community interests (i.e., allegiance to a foreign land, the Pope, or an Imam). For instance, African-Americans and Asian-immigrants were long denied citizenship on the grounds that either they were irrational, or their loyalties were attached to foreign governments. Most countries have procedures to offer personhood to aliens through naturalization toward citizenship, but fulfilling obligations through military service is often quite effective (Janoski, 2010; Brubaker, 1992). However, many European countries give aliens the right to vote in local elections, despite a seeming denial of personhood.

According to some definitions of citizenship that are based on personhood, 'competence' is a defining feature. Under these criteria, certain disabled or other socially excluded individuals may be denied full citizenship status by law. For example, working class men who were uneducated in seventeenth century England faced a charge of incompetence, and they were also accused of having inadequate interests in protecting property since they had little or none. Similarly, during World War II, Japanese-Americans had their citizenship restricted first on the basis of their questionable competence as reasoned men. And in the two decades after World War II, African-Americans fought the civil rights movement for equal rights after they were nominally granted these rights in the Emancipation Proclamation and the 14th Amendment a century earlier. Increasingly, scholars in the race and ethnicity tradition have been embracing citizenship theory in order to better explain discrimination and prejudice (Gates et al., 2012; Roman, 2010; Somers, 2008). Glenn (2011: 3) recommends that we go beyond personhood as a legally deployed status, and focus more on how others require and construct recognition.

Establishing total or complete competence has been discarded with various physically and mentally challenged groups. While these groups have gone to great efforts to show that they are competent to various degrees, their claim is much more based on a human rights argument that all humans, no matter whether they are 'temporarily abled' or not, are entitled to rights or 'the least restricted environment.' This has also applied extensively to mentally ill persons who make claims to be treated with dignity and compassion in society. Another complication connected to competence, is that many of these challenged or mentally ill groups often require representation by people not in their group (i.e., parents, spouses, or other advocates). Occasionally, exceptional cases emerge such as Temple Grandin who has autism and is a professionally-trained veterinarian. But citizenship for these groups cannot rest on truly exceptional people. It must rely on all disabled citizens and the varieties of experiences that they bring to society through what David Matza calls 'natural deviance' (Carey, 2010).

Individuals can also be denied personhood on the basis of moral grounds. When individuals break the legal, political, social, or religious moral codes in society they are subject to sanctions. These sanctions may deprive them of certain individual citizenship privileges – implying that their behavior is unbecoming of morally civil human beings. For example, prisoners are denied their full entitlements as citizens even after they have served their punishment for violating the rights of others. Once they have paid their debt to society, they should have their rights restored. Similarly, lesbian, gay, bisexual, and transgender (LGBT) persons have been/are denied certain rights as full citizens – the most prominent being the right to marriage – on the basis of moral arguments against their sexual orientation (Fisher, 2008). To gain full personhood recognition, people from these groups have had to argue, demonstrate, or fulfill obligations to make the case for their moral and intellectual worth.

Women too, have long fought for equal rights, and the ways in which women gradually achieved political, civil, and social rights often followed a different pattern from that of men (Lister, 2010). Women have progressively legitimized their personhood through waves of feminist movements, which have served to highlight the gendered nature of state policy and the inadequate theorizing of mainstream citizenship, which ignores a female perspective and discounts the relevance of what happens in the private sphere. Going back to the US and British early nineteenth century, feminist actions brought to light the inequalities facing female citizens when labor policies and development strategies favored men. By the end of that century, feminist campaigns had successfully earned women in most countries the basic legal rights as citizens to vote, hold political office, and take part in the workforce. Moreover, the growing influence of women in public discourse confronted traditionally patriarchal structures of the state, in which

healthy, working citizens are defined in masculine terms. Consequently, as women gain status as a significant interest group, so do the primary issues that concern them, such as health care, maternity rights, birth control and abortion, labor market discrimination, secure housing, infant and old age care, and education (Misra and King, 2005: 529).

Some, including many feminists, see citizenship as being unduly relegated to the public sphere when most of the fight for women's rights concern trying to regulate what goes on in the private sphere (Lister, 2010). Lister suggests that the powerful public–private dichotomy is deeply gendered, and has meant that women's admission to citizenship has been on male terms (Lister, 2003). A feminist perspective regards citizenship as contested; and as a concept in which the legal rights discourse is individualistic and male-inspired. According to Lister (2010) we need a revised discussion of the rights and duties of citizenship in order to acknowledge the performance of men and women's share of work/care in the private realm as a part of a general citizen's obligation.

As has been the case for women, minority racial groups, LGBT persons, and immigrants, the dominant power holders initially discredit all 'new' groups seeking citizenship. There are many discredited groups in society that successfully or unsuccessfully pursue personhood. Pedophiles are one such group generally regarded as being morally reprehensible and devoid of full personhood status – even in prisons where they are singled out for punishment by their fellow prisoners. Sexually abusing children is strongly condemned in most contemporary societies. However, there are variations between countries about the age at which childhood ends, which impact on someone being defined as a child. Beyond those doubts, some could argue that pedophilia is a disease, thus giving pedophiles a right to treatment in their communities and a restoration of personhood and citizenship rights. The medicalization of pedophilia could remove the stigma that is attached to this condition and they could then regain moral standing. In other words, the acceptance or denial of citizenship is heavily dependent on the messy criteria for defining personhood. This case would test the bounds of personhood and how much we might expand the concept of citizen behaviors.

Universal/Particular Rights and Individual/Group Rights

Citizenships rights can be extended to individuals, and also to groups. Following its strong liberal roots, citizenship is most often based on the allocation of individualistic rights that are universally available to all. This approach ensures that conflict between rights and obligations are relatively easy to resolve on a one-to-one or government-to-one basis. Group rights, on the other hand, tend to be framed in connection to honoring diverse human or cultural rights and are allocated to groups of people, not individuals. Theoretically, there are three levels of viewing this latter distinction (Janoski, 1998; Leydet, 2011).

First, many liberal countries have given rights to cultural or linguistic minority populations. For example, in the US, group rights are available to Native American tribes and to Amish dissenting communities who may exist in a separate community – sometimes upholding their own legal system. This protects their more communitarian culture from the individualistic ravages of general liberal society. In Canada and Belgium, similar group rights belong to linguistically defined communities such as the Québécois, Nunavut, Walloon, or the Flemish.

Second, neo-corporatist and social democratic theory gives very strong group rights to labor unions, who gain identity by encircling a large percentage of the population. One example of this is the neo-corporatist structure of bargaining where labor, management, and the state bargain over basic wage structures and the level of work. An example of this is reflected in South Africa's incorporation of the Congress of South African Trade Unions (COSATU) into the nation's parliamentary governance structure. This is particularly effective where 80–90% of the workforce is represented by unions as in Sweden.

Third, communitarianism advocates for multiplex group rights in societies that can be divided up into many subgroups. Communitarianism emphasizes the protection of subcultures, and places importance on obligations over and above individualistic rights. Will Kymlicka (1995) offers a strong example of communitarianism, and is a strong proponent of group rights for immigrant subpopulations in France and Canada. Perhaps, more controversially – such is the argument made by the South African Congress of Traditional Leaders (COTL) – a communitarian vision is one in which the purpose of the nation-state is to accord ethnic groups sovereign autonomy over their realms. In other words, the state functions to "put the dictates of indigeneity before the universal rights of citizens" (Comaroff and Comaroff, 2009: 3). Group rights work best with members living in tightly knit communities where there is little influence from the outside. A cosmopolitan community would increase the conflicts between exclusive rights.

Internal versus External Boundaries

The concept of citizenship has a socially defining characteristic, by ordering people into 'in' and 'out' groups. Rogers Brubaker (1992) addressed the closed nature of citizenship by employing Max Weber's reasoning that one can only have an exclusive status such as citizenship if others do not have it. This resulted in some disputes over citizenship versus human rights. If everyone is a citizen of the world with human rights, how might such a system be enforced? The common answer is that nation-states enforce citizenship rights, and as a result, they do not enforce rights for non-citizens. Hence, citizenship belongs to the nation-state. A large body of literature has developed to cover the processes of naturalization, by which external immigrants become internal citizens (Janoski, 2010; Joppke, 2005).

Four main challenges have emerged to the nation-state being the keeper of internal citizenship status. First, the ability to hold dual citizenships challenged the exclusivity of national membership. As nation-states gradually dropped the insistence that wives take their husband's citizenship, this allowed women to hold two nationalities, and subsequently opened the door for children born from these unions to also lay claim to citizenship in two countries. The Cold War kept a lid on these processes since soldiers were expected to have exclusive

loyalty to one country, but as communism fell, and air travel expanded, states began to liberalize their dual citizenship provisions (Kivisto and Faist, 2008).

The second major challenge to the exclusivity of nation-state citizenship was the formation of the European Union (EU). When the EU developed its unified labor market provisions and recognized citizenship for all members of the EU, it reimagined the purposes of national borders and passports, allowing for a new context of transnational labor, currency creation, economic flows, and citizenship rights. People living within the union could get a job anywhere they wanted in the EU, and their rights could be protected, no matter which EU country they were working in. This fits the concept of a 'transnational state' enforcing citizenship rights (Bauböck, 2003).

Third, the globalization of business and the ability to own property in many countries throughout the world has transformed traditional understandings of national citizenship. Transnationalism has flourished in the global capitalist economy, especially among the Chinese and Indian diaspora, which proliferate throughout Southeast Asia, parts of Africa, and the Americas. In this context, dual citizenship is much sought after. Although holding multiple citizenships are not a requirement for conducting international trade, it certainly eases the burden of travel, passport control, visa applications, and property ownership. Aihwa Ong (2006) contends that transnational citizenship transcends political boundaries for the sake of more effective economic transactions. Ong (2006) connects citizenship to neoliberalism by describing this ideology as an incredibly 'malleable technology of governing,' which can be used in different ways to suit authoritarian, democratic, or communist regimes. As a result, Southeastern and Eastern Asian states are changing their practices to compete more effectively in the global economy.

Furthermore, these perspectives were especially 'interested' in the presentation of self and identities that might develop with these multiple interactions, with formal status for each one. Thus transnational citizenship could include participating in the civic associations and voting in multiple 'interested' countries. Sometimes countries have particular interests in satisfying their diaspora, so that they will continue to send money and remittances back to the home country. Maintaining their original citizenship is one way to do this. But 'sending' countries have also hampered their immigrants in obtaining new citizenship, by causing them to lose property at home if they naturalized to the 'receiving' country. But in the prominent cases of Turkey and Mexico, these restrictions were recently loosened.

The fourth challenge to nation-bound citizenship comes with the emergence of the international aid movement in the development era. In this worldview, every person is a 'global citizen' and is responsible for being civically engaged with matters that concern all of humanity – no matter in which country they take place – such as environmental degradation in the Amazon basin or starving children in Sudan. The concept of cosmopolitanism presents a one-world view, in which every person is a member. This approach has garnered a lot of support from international organizations defending the rights of people in many different countries. International nongovernmental organizations may provide civil surveillance services or act as moral watchdogs (e.g., Amnesty International and Human Rights Watch); or they may provide basic services that protect human rights (e.g., Doctors without Borders and the Red Cross providing health care, food, shelter and other aid to refugees and needy persons throughout the world). The United Nations High Commissioner for Refugees is one instance where the UN takes a strong role in this area.

Status as a global citizen is still highly abstract, and although the League of Nations issued Nansen passports after World War I, the UN has never officially engaged in issuing anything like a world passport. Hence, global or cosmopolitan citizenship usually involves an individual holding multiple-country passports – they are legally citizens of many countries. However, governments disagree about the legitimacy of these individuals, and many are reluctant to issue citizenship to an individual who already has more than one nationality. Despite holding multiple passports, governments can restrict entry to certain people through the issuances of visas. Some countries have downplayed the visa process to the point that visitors – or certain visitors – do not need entry visas. Other countries, like China and Russia have strict visa requirements and are very careful about who comes into their territory and who leaves. Furthermore, China is extremely suspect of cosmopolitan citizenship and does not accept dual nationality, except under very limited conditions. The US does not officially recognize dual citizenship but allows it for children and even recommends informal (but illegal) acceptance i.e., "don't tell us if you did not actually drop your other citizenships" (Kivisto and Faist, 2008; Ong, 1999, 2006; Held, 2010).

Consequently, transnational citizenship is limited to smaller and more ambitious countries in Southeast Asia. Other than the European Union, no supranational entity, or unified set of nations, has bestowed citizenship if an individual nation-state is not willing to do so. Refugees face a precarious situation and the world's nation-states are increasingly resistant to accepting refugees. Jordan, with the world's highest per capita refugee population, is stretched to the limit and there are few countries stepping up to help the Jordanians take care of these individuals.

While not necessarily connected to transnational citizenship, the UN has had a strong impact on nation-states in terms of developing treaties that support various rights of groups, categories of people, and individuals. For example, the UN adopted the International Covenant on Civil and Political Rights, and the International Covenant on Economic, Social, and Cultural Rights in 1966. It has passed other conventions on racial discrimination, women's rights, torture, rights of the child, rights for those with disabilities, and the rights of migrant workers. The Geneva Conventions enacted between 1865 and 1949, and the UN Human Rights Council established in 2006, deal primarily with Human Rights issues, but also with matters of citizenship. While laudable, most of these covenants and conventions need considerable bolstering before they have an enforcement mechanism, and many countries, like the US, don't sign and ratify many of them.

Citizenship Variations in Regime Types

One could hardly expect citizenship rights, obligations, and processes to be the same in all countries across the different continents. Societies vary considerably on the set of citizenship

rights that they offer to their people, and in terms of the institutions that they set up to deal with these agreements. In many ways this often overlaps with various theories of civil society. Studies using an historical time-series analysis, in contrast to a comparative approach, have yielded great insight into the different country conceptions and implementations of citizenship.

Gøsta Esping-Andersen developed a major contribution to citizenship when he came up with the idea of three welfare state regimes under capitalism. He showed quantifiably that welfare states differed consistently between liberal (e.g., US, UK, etc.), traditional (e.g., Germany, France, etc.), and social democratic (e.g., Sweden, the Netherlands, etc.). The average scores for various welfare state characteristics varied considerably, as did the state structure in their level of expenditures, and the way that they structured their institutions for each program. For instance, liberal regimes provide means-tested (i.e., testing for low income) benefits whereas social democratic regimes share benefits with all. Traditional regime pensions rely on insurance programs particular to industrial sectors that are highly regulated by the state, but liberal regime public pensions pay little and workers rely more on private sector pensions that are lightly regulated.

Based on Gøsta Esping-Anderson's (1990) empirically grounded categorization of welfare state, Janoski (1998) constructs a theory of individualized or generalized citizenship regimes. He contends that in 'liberal regimes,' strong legal and moderate political rights protect property and business culture, and uphold a small welfare state. 'Social democratic regimes' tend to support worker organization, the labor force, and very strong welfare protection for all. And 'traditional regimes' have moderate-strong welfare states but they are closed off to protect these gains, and the society has a strong sense of mutual obligation, which lowers or distances interest in transnational human rights. Janoski (2010) followed this up with standardized measurements for these citizenship regime types based on nationality and citizenship laws. These were somewhat different regimes with colonizer (e.g., France and the UK), noncolonizer (e.g., Germany and Italy), settler (e.g., the US, Australia, Canada, etc.), and Scandinavian countries (e.g., Sweden, Norway, etc.).

But there are considerable challenges to measuring citizenship regimes when one moves to countries outside the traditional OECD group of nation-states. In China under Mao, citizenship was a layered construction favoring workers of the privileged state organized enterprises (SOE). These organizations basically operated as the arms of a welfare state, providing the full range of social rights including housing, food, education, and medical care – the 'iron rice bowl.' At the same time, political and legal rights were highly constrained and subject to highly negative sanctions with dissidents sent to jail or killed; and citizenship was segregated between rural and urban environments. In rural villages, citizenship was more akin to subjecthood, with farmers belonging to collectives and families fully supporting themselves without relying on the state at all.

With the opening up of China and its subsequent economic development, this bifurcation remained but in a highly modified form. The cities still have higher citizenship rights; however, the SOEs – except in the areas of energy and utilities – have largely collapsed and their former workers fight for pensions and wages. Nonetheless, wages and benefits have remained higher in the cities and much lower in the villages. The Chinese government has instituted the *Hukou* internal passport system to control the movement of people in the country. When villagers move to the urban areas to work in the factories of the specialized economic zones, their rights do not take effect in the cities. In practice, they become second-class citizens without many pension and housing rights, access only to a secondary form of emergency health care, and they cannot send their children to urban schools. Their situation largely resembles that of illegal aliens in the US, although civic resistance to these norms is growing in China.

In Africa where multiple 'citizenships' coexist, the boundaries separating legitimate members from the rest are murky, and the extension of rights to all individuals and groups may exist in theory but not in practice. This plays out in a scenario where citizenship is officially associated with national identity, but unofficially associated with an ethnic subpopulation. For instance, in many African nations, citizenship rights are extended to all country nationals but also to tribal groups – some of which hold considerable social and political clout. Consequently, two systems of power are institutionalized under a single authority: one urban, based on civil power and rights; and the other rural, where tradition and culture incorporate customary rule. What emerges are two simultaneous systems of direct and indirect rule that correspond to two kinds of citizenship.

This institutionalized bifurcated state, tends to fragment citizenship and civil society along class and ethnic lines, as well as along rural and urban divides (Mamdani, 1996). Rural, tribal dwellers may hold all legal rights of citizenship that correspond to that of their urban counterparts, but in practice, their 'tribal citizenship' may discourage/prevent their full participation in democratic nation-building processes. Similar sets of processes play out for Palestinians who are citizens of the Israeli state but largely prevented from exercising various political rights.

Citizenship as a Process or Activity

There is a moral aspect of citizenship that is somewhat differently conceived from citizenship as a status or an identity. Often, this moral framework refers to cultural notions of 'being a good citizen,' which has two meanings. First, there is an expectation that individuals obey the law and fulfill the required legal obligations that are associated with being a citizen. For instance, a good citizen is not a criminal, a terrorist, or a rebel who intends to bring down the state. The second meaning refers to cultural expectations of morally appropriate actions, such that a good citizen is someone who participates in voluntary associations; someone who volunteers to help his/her community; and someone who generally behaves in ways that better the community. In other words, citizenship is more than a state of being; it is also an action or a process of doing.

Engin Isin (2008, 2012) regards citizenship as a socialization process in the development of citizenship consciousness. Class, race, ethnicity, nationality, gender, family structure, or even place act as determinants of citizenship consciousness by shaping individual learning about voting practice, governance

structures, laws and obligations, and political participation. Isin et al. (2008) contest the conception of citizenship as merely a status; they widen it to include social struggles for recognition, or civic claims by groups and individuals to gain more rights. Citizenship becomes an outcome of interaction processes between those who belong and those struggling to gain access.

In the process of becoming a citizen through birth or naturalization, individuals learn and practice the norms and rituals of being a good citizen. Throughout this process it becomes clear that there rarely is a one-to-one, direct relationship between rights and obligations. For instance, the process of gaining rights may have no direct obligations because they are simply acquired at birth or at the age of majority. Moreover the required obligations are not always clearly distinguishable from rights (e.g., is voting a right or an obligation).

Consequently, citizens make individual choices about how to be citizens. For example, paying taxes is not a simple matter of a citizen fulfilling an obligation by writing out a check to the government. It also involves making many decisions about alternatives to taxation, such as investing in tax free municipal bonds or other tax-deferred accounts, avoiding taxes altogether by hiding money in offshore accounts, protesting about taxes, and so on. In other words, citizenship rights and obligations cannot be reduced to one little pinpoint in a spectrum of behaviors.

When citizenship is framed as a process, behavior and social interaction are moralized. This viewpoint extends the static theories of citizenship in constitutions and laws to include the social- and culture-shaping of citizenship. And as such, citizenship becomes a centrally strategic concept in the analysis of identity formation, civic participation, human rights, and engaged political life (Isin et al., 2008). Hence studying citizenship becomes study of these sorts of processes. Isin and Turner (2002) suggest that one should conceptually frame citizenship around three fundamental axes: extent, content, and depth. The nation-state demarcates the extent of citizenship through rules, laws, and other boundaries. Content looks at how rights and obligations are defined and combined into the actual process of citizenship. And the depth of citizenship refers to how much the practice of citizenship penetrates into the daily lives of individuals.

Citizenship and the Media in the Future

The discipline of sociology pays particular attention to the changing social landscapes of human action. With the rise in popularity of electronic social platforms, and the increase in technology-driven methods of communication, some sociologists began to theorize a new domain of electronic citizenship. According to Gavin Newsome (2013), who has developed the concept of 'citizenville,' individuals already supersede existing avenues of participatory citizenry by using their easily accessible mobile telephones and computers to record/access information and rapidly share it with people in their networks via Twitter and Facebook. He asks the question: "Why is it that people are more engaged than ever with each other – through Twitter, Pinterest, Facebook, text messaging – but less engaged with their government?" During the early Arab Spring movements starting in 2011, civil resistance was spurred on by thousands of individuals tweeting and filming live commentary from the frontlines using their mobile phones. They were engaging with people from all over the world in an online 'citizenville.'

Newsome's argument is that electronic communities approximate real-life citizenship, but in 'citizenville,' individuals have the added benefit of amassing real-life points by doing 'real-life good.' Newsome (2013) highlights five themes that characterize an electronic participation process: government becomes transparent; people use data to create useful apps, devices, and tools; digital aliens and immigrants are made into digital natives; people are allowed to bypass government by taking matters into their own hands; and the process of governing will become much more innovative and entrepreneurial. In the near future, we may more or less become the citizens of Facebook, YouTube, and Twitter.

In this new view of citizenship, there will be some casualties. Luddites and the technologically adverse, or those individuals and organizations whose identities are hacked or breached, will fall victim to the failure of citizenville to guarantee safety. But in actuality, the impact on the first two categories of people will be ignored; while the last one can be countered by having all individuals becoming defended by cloud- or crowd-sourced surveillance. According to this perspective, the political system becomes more voluntary as civil society grows fully interactive and transcends political and economic boundaries. In this decentralized, networked structure, the emergent political order is achieved through local politicians, like mayors, and not through top–down authorities like a president or executive bureaucracies.

However, one might look at this quite differently if we substituted 'computer technology' with 'genetically modified seeds' or 'cloning' for the web. A more serious problem is citizenville's lack of concern for corporations, who after all, tend to erect walls both geographically and economically to parse out how much money goes to owners and how much goes to citizens. Do we believe that these 'Goliaths' of ownership would just let these 'Davids' run the world?

City Marketing

John Rennie Short, University of Maryland Baltimore County, Baltimore, MD, USA

Abstract

Since the 1970s city marketing has grown in size and importance. A historical contextualization considers the selling of the frontier city, the resort, the suburb, and the industrial city. The article explores the symbolic reconstruction of cities through a discussion of strategies and tactics of city marketing. Marketing strategies include the promotion of the postindustrial city, the global city, the business city, the good city, the green city, the cosmopolitan city, and the city of culture. The tactics of city marketing include namings, slogans, logos, and the construction of iconic buildings. The article discusses what city marketing reveals about social power in cities.

In 2011, officials from the Russian city of Yekaterinburgh submitted a nomination to the Bureau of International Exhibitions to host Expo 2020. It was part of a marketing campaign to rebrand the city that also included a renaming. During the Soviet years the city was called Sverdlovsk; it was a military–industrial city closed to foreigners with entry into and out of the city strictly controlled. It was a closed city not only to visitors but also to discursive representations. It was a supposedly secret city, hidden from international view and global scrutiny. The city's name change and Expo 2020 application embody a more general trend, the marketing of cities to achieve recognition, to change the internal and external image of the city, and to connect to a global flow of positive urban images and upbeat urban imaginaries.

The Historical Context

The marketing of cities has a long history. For just the past 150 years Stephen Ward (1998) identifies several dominant marketing campaigns: selling the frontier town, the resort, the suburb, and the industrial city. We can consider examples from each category.

Marketing campaigns were important for emerging towns in territories opened up for capitalist investment as urban boosters had to convince people that the city, despite its youth, small size, and eccentric location, was on the verge of greatness, increased growth, and vast capital returns. The city needed to project an image to a world that did not know of its existence. In the US West, for example, in the latter half of the nineteenth century, advertisements were placed in newspapers in the populous east of the country and in Europe to attract investors and immigrants. An 1887 promotion map of Wichita, Kansas, for example, uses a subtle spatial distortion to depict the city in the center of the country. We can extend the notion of the frontier town to the contemporary era with the idea of cities emerging from the silences and obscurity created by political and economic exclusion from the wider capitalist world. After the fall of communism in 1989 and the 'opening' up of Eastern Europe and China in the past 20 years, many cities in these countries were suddenly open to foreign investment opportunities and needed to announce their presence and position themselves to attract global flows of investment and to achieve a more positive position in the global flow of urban images. The more the number of cities that marketed themselves the more pressure was placed on the remaining cities in what is described as *place wars*. Shanghai, for example, was marketed by promoting its long association with the wider world, as a cosmopolitan city reconnecting with the global circuits severed by Maoism. Its long cosmopolitan past was promoted. Yekaterinburgh is located more than 1000 miles east of Moscow and only recently emerging from its closed city status. Like a US frontier town in the late nineteenth century, it is seeking to hold an international event. St Louis held the World Fair and the Olympic Games in 1902. Yekaterinburgh applied to host Expo 2020. Hosting international events, constructing new buildings, and initiating urban development plans are important parts of 'frontier' town promotion because they also signal urban sophistication and dispel perceptions of provincialism and unconnectedness. The city authorities of frontier towns such as Denver and Kansas City, desperate to show their sophistication, eagerly adopted the City Beautiful movement of the 1890s that stressed neoclassical architecture, grand vistas, and ambitious landscape designs. Here we can make a more general point. New architectural fashions such as City Beautiful, modernism, or postmodernism are not only shifts in design but also vehicles for city marketing as cities use the new fashions to signal their cutting edge character and the extent to which they are engaged with contemporary fashion and plugged into the most global circuits of innovative architectural design. Constructing a new building in the latest style is an important form of city marketing.

As mass tourism developed in the middle of the nineteenth century, a new category of consumer was created: those searching for play and recreation. Cities responded to the new market by selling themselves as sites of pleasure and entertainment. The city of Blackpool in England advertised itself through a variety of means including building Blackpool Tower to provide an iconic image and elaborate illuminations to extend the season beyond the summer into the longer nights of winter. As the tourist gaze has widened, more cities from around the world are brought into the range of possible destinations. Consider the example of Budapest that emerged from communist domination in 1989. The rebranding of the city from communist city to postcommunist city open for business and tourism was hampered by municipal

fragmentation; however, a Budapest City Identity Office was opened in 2006. Emphasis was placed on attracting tourists, and within that sector particular emphasis was placed on heritage tourism highlighting the historic nature of the city and its architectural legacy (Smith and Puczko, 2010; Szondi, 2011). Niche marketing of tourist cities reflects the variegated market demand. At one extreme are the child-orientated family-friendly destinations such as theme parks. At the other extreme, certain cities sell an image of adult sexual tolerance. Phil Hubbard (2012) documents a number of cases, including San Francisco, Sydney, and Cape Town, of the self-conscious marketing of a gay-friendly city with emphasis on safe gay spaces. For the past 10 years Las Vegas was marketed with the phrase, 'what happens in Las Vegas, stays in Las Vegas,' as an explicit attempt to target an adult market. From the promotion of the genteel spa towns of yesterday to the representation of uninhibited and available sexual pleasure of today's cities, the marketing of the resort city continues. It has widened so that resort cities compete for global markets, both intensifying the competition and homogenizing the set of marketing images for similar destination types. A standard repertoire of images includes beach and sun, play and recreation, escape and discovery, culture and learning, and freedom from the constraints of the ordinary and the banal. The image of the 'exotic' holiday destination also arises as the widening tourist range makes ever more distant cities more available. The global tourist gaze now evaluates urban destinations around the world.

Mass suburbs appear in the mid-nineteenth century. As a new urban form, a market for suburban living had to be created as much as met. Suburbs had to be sold to people long used to living close to the city. In the preauto, walking city, higher income groups lived closest to the center; the poor were banished to the outskirts, forced to travel further and longer. The suburbs represented a new form. While transport improvements shrunk distance, making suburban living more accessible, the newness of the suburbs required image control. The new suburbs of the wealthy needed careful attention. They were sold and marketed as places of exclusivity. To maintain the perception and reality, restrictive covenants were widely advertized and often strictly enforced. In a perceptive study Robert Fogelson (2005) examines the heavy restrictions in US middle and upper income suburbia from 1870 to 1930. He shows that restrictive covenants were a nationwide phenomenon as developers and homeowners sought to minimize any changes that would undermine land values, house prices, and social exclusivity. The restrictive suburbs were envisioned and marketed as a haven of peace and tranquility from all this threatening change.

While suburbanization is now a fact of life, marketing individual suburbs continues. Three themes can be identified that center on the idea of the suburbs as place of retreat. The first is the depiction of the suburb as rural idyll. A massive residential development along Britain's M4 growth corridor was initiated in the 1980s (Short et al., 1986). The development was subdivided into neighborhoods. Part of the marketing involved the self-conscious naming of these neighborhoods. Names such Badger's Walk, Miller's Green, Upper Wood, Meadow Vale, and Swallow's Meadow all sought to evoke the warmth and comfort of the rural preindustrial past. The names evoke a quiet and stable community in a region of noise and rapid change. The second theme, especially important in cities in developing countries, is the evocation of global connections to signal modernity and sophistication. New suburban developments in Shanghai, for example, are called Australia House, Scotland, and Manhattan. These British and United States inspired names represent a marketing of the modern, the international, and the cosmopolitan. Finally, there is a marketing of certain suburbs as gated communities. The gates signal privacy and security. They are a message meant to quiet fears as much as to initiate purchase. The development of gated communities in cities round the world is as much about marketing as actual security. The gates and the guards are meant to reduce urban anxieties of newly emerging middle and upper income groups.

The industrial city emerged in the early nineteenth century. Cities such as Manchester, England, were the crucibles for the creation of an urban industrial economy. Industry was long fixed in place, tied to sources of power, skilled labor, capital, and social networks. In the past 150 years the mobility of industry has increased, freed from the locational constraints of the past. Electricity provides a more dispersed energy, and deskilling and mechanization of the industrial labor process has reduced the pulling power and influence of skilled labor. A globalizing world is embodied in the growing mobility of industry that creates a space of opportunity for newer cities to market themselves as industrial cities. In the Untied States, for example, cities in the Sunbelt long sold themselves as cheaper places to do business. Atlanta has marketed itself to northern and international investors as a place to do business since the late nineteenth century. In a globalized economy the range of industrial cities has widened to include much of the developing world. Since 2003, the city of Ahmedabad, in Gujarat, India, is promoted through a biennial event, the *Vibrant Gujarat: Global Investors Summit*, which targets foreign direct investors, rapidly growing Indian companies, and on-resident Indians with US business interests. The summit aims to strengthen confidence in the state and the city (Nair, 2011).

The promotion of an industrial city revolves around a number of themes: the city as a probusiness environment of low taxes with a skilled, stable, and cheap labor force; good infrastructure; and locational advantages of easy access to regional, national, and global markets. Bailey (1989) suggests a three-stage evolutionary model in the marketing of the industrial city. The first stage, *smokestack chasing*, involves attracting industries on the promise of low operating costs and higher profits. The second, *target marketing*, involves the attraction of industries enjoying profitable growth. Finally, *product development*, folds the first two into a more ambitious strategy to attract the inward investment of cutting edge manufacturing. Marketing shifts through the stages from highlighting lower operating costs in the early stages to greater emphasis on skilled labor, global competitiveness, and quality of life in the later stages.

City marketing is now an important global phenomenon. In the rest of this article I explore the strategies and tactics of contemporary city marketing. A discussion of strategies allows us to answer the question of why cities are being marketed. The

analysis of tactics enables us to ask how cities are being marketed. I will discuss a number of examples in some detail and end with a critical discussion of evaluating effects and noting silences. These latter two points address the issue of what is the result of the marketing and what is left out.

Marketing Strategies

Cities are marketed in order to enhance, improve, and/or change their image, either internally or externally and sometimes both. The term branding is also used, although it is more usefully applied to a specific campaign for an individual city that marks it out as distinctive. There is now substantial literature on city marketing. David Gertner (2011) identifies over 259 articles produced by 280 authors in 43 different journals over the past 20 years.

While each individual city has a unique aim in mind, specific to the city, there are a number of more general strategies that can be identified across a range of cities. They are not mutually exclusive as many cities, especially the very largest cities, project a complex, and sometimes dissident, set of images to the wider world. I discuss seven basic strategies of marketing: promoting the image of the postindustrial city, the global city, the business city, the good city, the green city, the cosmopolitan city, and the city of culture. The divisions between them are fluid and porous. They are best considered as an assemblage of positive urban images that city boosters seek to represent. The most successful and ambitious cities seek to combine most of them, if not all, in one positive urban imaginary. Cities can be ranked by their ability to embody the largest number of elements of this urban imaginary assemblage.

The Postindustrial City

In the wake of deindustrialization of large swathes of urban North America, Australia, and Europe, formerly industrial cities were placed in the unenviable position of losing investment, jobs, and identity. The global shift of manufacturing creates new industrial cities in the developing world but leaves behind industrial cities in the developed world. These industrial cities, or to be more accurate, these newly postindustrial cities, became associated with the old, the polluted, the past, and the failed. A major theme of marketing these postindustrial cities is to distance them from their recent industrial past. Some of the rebranded postindustrial US cities include Pittsburgh and Syracuse. In the case of Syracuse, New York, this involved a new logo for the city that replaced images of smoking factories with postmodern building skyline and a transformation of a local lake from dump site to scene of regeneration and set of recreational opportunities (Short et al., 1993). Formerly industrial cities are rebranded in more attractive packages that emphasize the new rather than the old, the fashionably postmodern rather than the merely modern, the postindustrial rather than the industrial, consumption rather than production, and spectacle and fun rather than pollution and work. Take the case of Wollongong, an industrial city on the New South Wales coast of Australia. A massive steelworks dominated the urban economy. The steelworks shed 15 000 jobs from the early 1980s to the mid-1990s. The rate of job loss was only one major strand in negative imagery associated with the city in the national imagination and among foreign investors. City leaders decided to rebrand the city in the public imagination. An image campaign was built around the idea of 'innovation, creativity, and excellence' (Kerr et al., 2011). An important part of the campaign involved the steelworks planting half a million trees on its site while the council found funds to clean up the beaches and construct cycle ways. The greening of the city is now an integral part of a city's attempt to shed its hard industrial image for a softer postindustrial greener imagery.

The Global City

In a globalizing world the marketing of a city as a global city is now an important strategy. The intense and constant competition to attract advanced producer services is a crucial driver of city marketing campaigns. Because of the growing competition, there is constant need to upgrade and improve a city's image. At the top of the global hierarchy, as measured in terms of the concentration of advanced producer services, sits London and New York. Both cities actively position themselves as global cities. In 1965, New York hosted the World's Fair, and after a period of fiscal crisis and economic decline the city was rebranded in 1977 with the successful *I (heart) New York* campaign. In 2012, London hosted the Summer Olympics Games, and presented itself as a multicultural, cosmopolitan, cool city.

Kim and Short (2008) note that the rhetoric of global city branding is often associated with attempts to justify controversial and costly urban redevelopment projects, to justify tax incentives and business friendly economic policies, and to heighten multiculturalism and cosmopolitanism in the city.

Below the top tier of cities are a number of major cities that compete for dominance in their national or regional space. Darel Paul (2004, 2005) explores the politics of 'global imagineering' in Montreal, Canada, where business interests triumphed, and Minneapolis–St Paul, USA, where similar interests where trumped by populist politics. In St Petersburg, Russia, not only was the old Soviet name of Leningrad dropped but the city was also actively promoted as an international hub of circulatory capital, host to corporate power, and stage for globalist megaprojects. St Petersburg was rebranded as an entrepreneurial, economically competitive, globally connected city (Golubchikov, 2010).

From 1997 to 2007, Honk Hong was specifically marketed as 'Asia's World City' (Shen, 2010). In his critical assessment Stephen Chu (2011) argues that the marketing highlighted the global at the expense of Hong Kong's local creative industries and vernacular hybrid cultures. Emphasizing the global was at the expense of the local.

The Business City

In a capitalist world economy of mobile capital and rapid redirections of investment flows, cities need to promote themselves as probusiness and friendly to capital. Short and Kim (1998) examined the advertisements of US cities in the

business press. Many cities explicitly cited the term 'business' to reinforce the message. The following are some examples:

Dallas	The city of choice for business
Milwaukee	The city that works for your business
New York	The business city that never sleeps
Phoenix	Moving business in the right direction

As capital becomes ever more mobile, more cities enter the competition, so cities need to aggressively promote themselves as good places to do business. More specific themes around this general message include emphasizing a probusiness political climate, a skilled labor force, good infrastructure, and accessible location.

The Good City

It is not enough to market a city's low costs. Cheap labor, for example, can also be associated with poor urban conditions; so cities need to highlight their quality of life. The case study of magazine advertising by Short and Kim (1998) identified a number of specific quality of life themes. These included friendliness, readily available and good quality health services, heritage, cultural amenities, and low cost of living. Investors, tourists, and visitors need to be reassured that the city is a decent place to live, work, and visit.

The case for selling this message to tourists and visitors is self-evident. The needs of business are more complex. While businesses often require low operating costs to maximize profits, they also require stable social conditions, a skilled and happy workforce, and a range of good-quality urban public goods and services such as decent health care. There are also the more pragmatic arguments that business executives may need to follow the inward investment and live in the city. Promoting the city as a good place to live is an important business strategy as well as vital to secure visitors such as conventioneers and tourists.

The Green City

The green city has emerged in the past two decades as an important element in city marketing and urban promotion. To some extent the term green is a loose and wide adjective that indicates a variety of ideas and images including good air quality, low pollution, sustainable urbanism, and accessible and attractive green spaces. The greening of a city can be an important part of promoting the idea of global city since the acceptance in principle, if not in hard practical application, of a green urbanism is now widely shared. It has also become a signifier of development and sophistication. Poor air quality is a sign of low-grade industrialization and unfettered environmental pollution. A green city is now considered a competitive urban advantage. Mexico City, long troubled by poor air quality, now boasts three vertical gardens, giant green walls of 50 000 plants that create shade, absorb pollution, and oxygenate the air. They are the lungs of the city. The living sculptures are the result of a public–private partnership that embodies the new civic consciousness of creating a greener city. In Seoul, another megacity long afflicted with poor air quality, the city government created more green spaces, cheaper public transport, greater use of fuel-efficient cars, and constant monitoring and policing of emissions from factories, cars, and residences. The result is not only a vast improvement in air quality but also a repositioning of Seoul as a global greening city.

The green image takes a number of forms. Seoul's relentless marketing of itself as a global city now incorporates a specifically green theme. It is part of what Blaž Križnik (2011) describes as the *symbolic reconstruction of the city* to stress tourist attractions of global competitiveness. A central part of the strategy was the reconstruction of Cheonggyecheon, an 11-km stream covered up by rapid urban expansion; it was the site of an elevated motor expressway. In 2002, the city government announced plans to demolish the expressway and reconstruct the stream as a green corridor. It was part of a downtown redevelopment plan that also signified a green and attractive Seoul, a global city with the requisite green credentials to go up against the leading cities in the world, part of what Ong (2011) describes as worlding practice.

The Cosmopolitan City

In a globalizing economy it is important to widen the appeal of city and the global competiveness of its goods and services. Cosmopolitan cities appeal to a wider range of investors, migrants, and tourists. The fostering and representation of a cosmopolitan city is now an integral part of the global city imaginary, alongside a probusiness environment and good infrastructure. Cosmopolitanism is now a vital part of the marketing of wannabe global cities. Some cities, such as London and New York, with large immigrant populations, have an inbuilt advantage. Others have to work at it. In Seoul, for example, the reality of a racially homogeneous city and nation meant that a city marketing campaign in 2009 under the slogan of 'Infinitely Yours' had to stress cultural diversity. Tolerance is now seen not only as a civic virtue but also as an important element in the formation and reproduction of the creative city. Marketing a city as cosmopolitan connects with issues of creativity and highlights the ability of the city to generate and attract the leading edge of the cultural creative economies.

Successful cities need to draw upon the global talent pool of labor, especially for the advanced producer services. Selling the city as a tolerant cosmopolitan place makes it easier to attract such labor. Some cities use cosmopolitanism in their marketing. Sheffield in England uses the slogan 'Where everyone matters' (Paganoni, 2012), Amsterdam explicitly used an English rather than a Dutch slogan, 'I am Amsterdam' to signal its linguistic openness (Kavaratzis and Ashworth, 2007), and Trieste promoted multiculturalism during its bid to host the 2008 World Expo (Colombino, 2009).

The Cultural City

An important part of the assemblage of the urban imaginary is the notion of the city as a place of culture, a site of cultural sophistication and a place of cultural practices. Perhaps the most famous case study is the successful rebranding of the city of Bilbao, an old industrial city in the Basque region of Spain,

after the opening of the Frank Gehry-designed Bilbao Guggenheim Museum. The so-called Bilbao effect is the uptick of tourists and investment in the wake of cultural promotion. We also have examples of less successful rebranding such as the case of Rotterdam, which hosted the Cultural Capital of Europe in 2001 yet failed to shift its image as working city (Richards and Wilson, 2004), or the relative failure to promote the cultural image of Milan (De Carlo et al., 2009).

The Tactics of City Marketing

There is now a large literature on the tactics of city marketing, the how of selling a city (Ashworth and Kavaratzis, 2010; Braun, 2008, 2012; Dinnie, 2011; Hanna and Rowley, 2012; Moilanen and Rainisto, 2009). We now have detailed case studies of individual cities ranging from Astana (in Kazakhstan) (Skok Hobbs, 2009), Bogota (Kalandides, 2011), Cleveland (Smith, 2011), New York (Greenberg, 2008), Taipei City (Karvelyte and Chiu, 2011); thematic studies, such as the marketing of smaller cities (Baker, 2012); the role of communication technology and city marketing (Gasco-Hernandez and Torres-Coronas, 2009); and the marketing of the cultural creative city (Harris and Williams, 2011; Haddock, 2010; Kennell, 2010). From this large body of work I will touch on only a few themes.

Marketing can involve namings. In the late eighteenth century the New Town of Edinburgh in Scotland was constructed. In the wake of the Jacobite Revolution against the British Crown, the good burghers of Edinburgh wanted to sell the city as an integral part of the British state. The main thoroughfares were named Queen Street, George Street, Princess Street, and Charlotte Square to forge a direct link the with royal family. In case anyone doubted the city's loyalty, one street was named Hanover Street after the royal family's German lineage.

Today, while naming remains important, the standard tactics of city marketing include the development of a media campaign, and the creation of a slogan or tagline and a logo or set of images. There are now companies that specialize in branding and city branding in particular. Agencies such as Brand Forensics, Corporate Edge, The Hamiltons, and Wolff Olins provide a one stop shopping for cities wanting to brand and rebrand themselves.

Key words are also employed in the slogan adapted by some cities. Here are some from Britain:

Dundee: changing for the future.
A safer, cleaner, ambitious Nottingham: a city we're all proud of.

While the slogan for Dundee is punchy and succinct, the one for Nottingham seems too long and disjointed. Slogans are often used in association with a logo, a visual punch line. The best known logo in the history of city marketing is the 'I (heart) NY' designed by Milton Glaser in 1977. The combination of the emotive heart sign and the geometric letters made for a winning design that was an important part of the successful turnaround in the rebranding of the city. Koller (2008) identifies at least six different types of logos based on different combinations of words and images. The city of Melbourne, for example, employed the design company Landor Associates to come up with a new logo to replace the confusing array of images employed to sell the city; their answer was to use the letter 'M' in variety of graphic designs to embody a singular city with multiple attractions. Short et al. (1993) looked at the rebranding of Syracuse when an image of smoking factories was replaced by an outline of a postindustrial, postmodern city. The slogan and the logo are most successful when they are part of an overall narrative of a marketing campaign. Thomas Sevcik (2011) suggests that city campaigns tend to use the same methods used to sell products, yet cities are more complex and need a more guiding narrative.

The outlets of city marketing include the traditional venues of print and television and increasingly the Internet. Peter Dobers and Anette Hallin (2009) discuss the use of the Web by city managers in Stockholm to promote the image of the city as 'The capital of Scandinavia.' Carl Grodach (2009) highlights the importance of promotional imagery on city homepages.

The marketing of cities can also involve the construction of buildings. Paul Knox (2012) writes about the importance of big-named architects, so-called starchitects, and the centrality of starchitecture to the symbolic capital of cities. To have a new building by a starchitect denotes cultural heft and global intentionality. Individual buildings and assemblages of certain built forms – museums, art galleries, new airports, and the like – built in the latest style by the hottest architects is an important way for a city to position itself. Perhaps the best known examples of branding through building are the Gulf States including Dubai and Abu Dhabi (Bagaeen, 2007; Kanna, 2011).

The hosting of events is now a significant part of marketing a city. So-called spotlight events highlight the city for a wider audience: the larger the event the greater the potential marketing opportunity. I have discussed at length the role of World fairs and Olympic Games in marketing cities (Short, 2012).

The hosting of events – such as film festivals, Expos, and Olympic Games – provides opportunities for a city's elites to stage a widely accessible and globally pervasive marketing campaign. In a detailed case study, Clair Colomb (2011) explores the marketing of Berlin between 1989 and 2011. She argues that the city was marketed through rebuilding and the staging of a new Berlin. In the inner city, sites were turned into tourist attractions. Place marketing and urban reinvention were intertwined in a symbolic politics of representation.

Most successful marketing campaigns involve some form of stakeholder involvement. On the surface this seems self-evident: get as many different interests as possible to buy into the selling of the city. City marketing just to outsiders fails to mobilize local support. However, stakeholder involvement can also generate conflict. Craig Hayden and Efe Sevin (2012), for example, highlight how the marketing of Ankara represents a collective representation that reveals conflicts and fractures well as shared ideas. Ooi and Pedersen (2010) show how the organizers of the Copenhagen Film Festival had different agendas from the brand authorities for the city, and Michele Acuto (2012) highlights the problem in successfully marketing the city of Sydney because of municipal fragmentation and the lack of a metropolitan authority.

The big question is, how affective are city marketing campaigns? There are obvious success stories. One of the most

cited is Barcelona. The success in attracting visitors and creating a positive buzz about the city is in part attributed to good marketing. In the wake of the successful hosting of the 1992 Olympic Games and the promotion of a cultural and especially an architectural legacy, the city is now perceived as cool and accessible, modern with an impressive cultural legacy. However, as Montserrat Pareja-Eastaway (2009) argues, whether this is due to marketing or the embracing and realization of long-term objectives by local actors is a moot point. This raises a more general issue. It has proved difficult to measure the independent role of city marketing in rebranding a city's image and turning around a city's economy. While we have some rough metrics (the Anholt-GfK Roper City Brands Index is based on 20 000 respondents in 20 countries responding to questions about cities), we have few detailed case studies. As one executive is alleged to have said, "I know that half of my advertising budget is a waste of money, I am just not sure which half."

Growing competition ensures that city élites need to be proactive in attracting and generating economic activity. City marketing may or may not work and may be good value or a waste of money, but in an increasingly competitive world it makes little difference. As more cities are marketed, pressure is placed on all cities to be marketed.

There is a growing body of critical work that highlights the silences of city marketing. The emphases of most marketing campaigns are on the city as a place of business, less on social inclusivity, more on the profitable city, and less on the fair and just city. The dominant themes represent the power of the dominant groups. The more marginal are excluded. In an interesting twist on this finding, however, Hernandez and Lopez (2011) suggest how slums can be used to positively brand a city, in this case Bogota. They suggest that highlighting rather than ignoring the city's slums assumes that one can invoke positive responses around ideas of genuine difference, cultural authenticity, and vernacular architecture. The poor and the marginal become less a political threat and more a marketing opportunity. In this case the ethos of marketing is so pervasive that even the silences are uttered and the problems exposed, not as issues to be solved or addressed, but as opportunities to sell and brand. The basic conclusion is that while it is questionable if marketing changes the image of a city, what is not questionable is that marketing represents the success of certain groups, especially political and economic elites, in having 'their' city represented and promoted in a manner friendly to their interests.

Civil Law

Abstract

The civil law is one of the large legal families in the world. It is widespread in Europe, Central and South America, and in many parts of Asia and Africa. It differs from other legal families not only in its defining history but also in its structure, application, and development. This article provides an introduction to some of its significant aspects and to its continued influence on the development of the law in various parts of the world. It also notes some of the differences in legal education and professional practice.

Structural Aspects

In the comparative study of law, legal systems are often seen as belonging to 'legal families.' These may be religious-based legal systems (for instance, Islamic and Judaic laws), they may be geographically or historically defined (for instance, tribal law on United States Indian reservations and the Roman law origins of Roman–Dutch law in South Africa), or they may be distinct because of their structure and methodology (the civil law and the common law) (see Zweigert and Kötz, 1998, pp. 63–73).

In particular, scholars frequently contrast the families of the common law and the civil law, which differ in terms of structure and methodology. This contrast holds despite the fact that both legal families have their roots in the Corpus Iuris Civilis of Justinian (AD 534, see *infra*). The common law has preserved some of these traditions to this day, while developing its own methodology. At the same time, the civil law has moved closer to the common law in some areas. Hence, the contrast may not be as stark today as it once was.

With respect to both families, it is dangerous to generalize: There can indeed be marked differences between legal systems belonging to the same 'family.' Thus, the use of codes (e.g., the Uniform Commercial Code (UCC)), the existence of a large body of statutory law, and the adoption of the influential Restatements (the summaries of prevailing case law, stylistically in statutory form, prepared by the American Law Institute, a private organization) may make the legal system of the United States appear closer to the civil law than to its English roots (see Farnsworth, 1996, p. 227). Such a conclusion, however, would misconceive the role and function of statutory law and of the methodology in its application in the civil law, on the one hand, and in common law legal systems on the other hand.

Codes and statutes consist of rules in all legal systems. These may be very specific, or they may be stated with some degree of generality. In some areas, common law codes and other legal texts display extraordinary detail, attempting to anticipate every eventuality. The common law judge, as a consequence, will begin with the factual circumstances of the case, and after examining, comparing, and weighing the factual elements of the case, will attempt to find a rule that fits it. This rule may be one of statutory law or derive from prior decisional law, including decisions authoritatively and bindingly interpreting and applying statutory law – the doctrine of *stare decisis* (Hay, 2010, p. 9, also *infra*). The civilian judge, in contrast, sees the case as a problem to be solved within the legal structure of the legal system. First, the problem at hand must be fitted into a legal category. Next, subcategories and sub-subcategories must be identified until 'legal rule' or 'concept' and the problem at hand match. Civilians proceed by deductive reasoning, while the common law approach employs an inductive methodology.

Categorization, as a structural characteristic of the civil law, also results in the drawing of sharp distinctions between different areas of the law. Private law deals with legal problems that arise between natural persons or between natural and legal persons (such as corporations), while public law (for instance, constitutional law, administrative law, and criminal law) addresses the relationship between citizen and state. In some civil law systems, this bifurcation results in the establishment of special courts to deal with these different areas of the law. In Germany, for instance, there are so-called ordinary courts with competence for private law and criminal law, and separate court systems with competence for questions of administrative law, labor law, and social law, with each system having its own supreme court. Since many cases will obviously involve mixed questions (e.g., of labor and private contract or tort law), there may be contradictory rules of law, with no unifying supreme court. In France, the *Conseil d'Etat* stands beside the *Cour de Cassation*, with exclusive competence in certain public fields of law. The exclusivity of the *Conseil's* competence avoids some of the German problems. Germany and Italy, for example, have constitutional courts, while most other civil law countries do not. While the divisions are more pronounced in Germany than elsewhere, categorization of fields of law and the establishment of specialized courts unavoidably leads to a high degree of specialization within the legal profession, among both lawyers and judges. These lines are much more fluid in common law countries.

The central role of the legal rule in civil law legal systems also explains why precedent (i.e., the binding effect of a prior court decision on a different, but similar subsequent case) is quite different from what it is in the common law. The civilian judge applies the law but is not bound (obviously with some exceptions) by earlier decisions of a higher court. In common law countries, in contrast, it is the decision of the highest court that ultimately is the law and therefore binds inferior

courts – the doctrine of *stare decisis*. Subsequent discussion will return to these points.

History

Roman law had no comprehensive codification before Justinian's Corpus Iuris Civilis. Law, such as it was, was divided into *iuscivile* and *iusgentium*. The former applied among Roman citizens; the latter applied to legal relationships among others (Romans and foreigners, foreigners among themselves, and slaves). Judicial functions were exercised by *praetores*. The *praetor peregrinus* administered the *iusgentium* and conceived and developed legal concepts unknown to the strict Roman *iuscivilis*. In a different context, of course, the English chancellor – at the beginning of the equity jurisprudence – performed equally creative functions. Similar ideas – for equity and judicial creativity – underlie the 'general clauses' of the civil law (see *infra*, p. 9).

With population growth and increasing urbanization, a new profession – that of the jurisconsult – arose. They were legal advisors who prepared written opinions for cases. As the number of opinions grew, principles could be derived from them that could be taught to students and serve as a basis for advice to judges. The development of principles fosters more abstract ways of thinking. Categories are conceived, and problems are classified for assignment to various categories. Under Emperor Justinian, opinions, decisions, and other materials were gathered and the Corpus Iuris Civilis was prepared.

The Corpus Iuris stands at the beginning of what Roman law means today. This code evolved in subsequent times as a result of the work of the glossators and commentators. These sources taken together constituted the 'Ius Commune,' the common law of Europe before countries and areas began to grow in different ways and today's 'different families' began to take shape. England developed the common law (although, especially in the early period, with many Roman law elements). The Scandinavian countries, France, and Germany had a leading role in developing the civil law. Once again, 'civil law' is not homogeneous. There are differences among civil law countries, and these differences are also reflected in the legal systems of those countries that modeled their codes or statutes after earlier rules of others. Two codifications in particular replaced the earlier 'Ius Commune' and proved very influential: the French code civil of 1804 and the German *Bürgerliches Gesetzbuch* of 1896 (see also the Austrian *Allgemeines Bürgerliches Gesetzbuch* of 1811). The French code not only influenced the development of legal systems in many European (especially Latin and Eastern) countries but also spread to the Near East, Central and South America, and even to parts of North America (e.g., Louisiana). The German code influenced the law of Eastern and Southern Europe (e.g., Hungary, the Czech Republic, Slovakia, former Yugoslavia, the Baltic States, and Greece) as well as of Japan and China (see Zweigert and Kötz, 1998; pp. 154–156). In 2010, the People's Republic of China promulgated a new law (effective in 2011) on the 'Application of Laws to Foreign-Related Civil Relations,' which mirrors modern European codification on private international law in many respects.

Roman law still exists in Southern Africa as Roman–Dutch law, an admixture of Roman law and old Dutch customary law that interacted with English common law (see Zweigert and Kötz, 1998, p. 232). Codification not only extended, in these and in other countries, to private law and private-law relationships but also encompassed criminal law, commercial law, and both civil (private) and criminal procedures.

Sources of Law

Primary Sources

Civil law systems draw a sharp distinction between primary and secondary sources. Primary sources are enacted law, custom, and 'general principles of law.' Of these, the main source is the enacted (statutory) law; it predominates in civil law systems.

A code in a civil law system consists of general principles, arranged in order of importance. At the beginning, there may be general rules regulating basic problems that need to be addressed before the particular problem can be analyzed. For example, if a plaintiff seeks damages for breach of contract, preliminary analysis must determine whether a contract was validly concluded. Provisions dealing with invalidity and avoidance of contracts usually are found in the general part of a civil code. Such a general part may be followed by particular parts dealing with individual fields of law, such as torts, contracts, property, or the law of succession. The main or basic codes are supplemented in increasing number by special statutes or codes of limited coverage with which the legal system reacts to new societal problems. Examples include consumer protection, telecommunication, and news media.

Custom is also a primary source of law. Customs are unwritten rules, developed and observed over years and now part of social and economic thinking. Customary law tends to be less important in practice because it is often difficult to prove its pervasive observance in society.

'General principles of law' are what the term expresses: Basic principles of the legal system that pervade it and derive from norms of positive law. Civil law judges resort to 'general principles of law' as guidelines in the interpretation of statutory norms both for the purpose of defining their interrelation and for their application. This is of particular importance when dealing with statutory norms that are rather abstract in their formulation. It is tempting to consider this process to be not very different from the case law methodology of the common law. There is an important difference, however. The common lawyer derives the appropriate rule by reliance on precedent and its interpretation and, only lacking precedent, resorts to general principles or to policy considerations. The civilian judge is not so restricted but derives the appropriate rule from the structure of the legal system and from the general principles of law that pervade it; nor will the decision in the present case have a necessary effect on later cases. This is not to say that later cases may not reach the same conclusion: At the point when decisions consistently reach the same result – what French lawyers call *jurisprudence constante* and German lawyers *ständige Rechtsprechung* – such decisional law may itself be regarded as having risen to the position of 'general principles of law.'

Secondary Sources

In the civil law, secondary sources consist of case law (see section Primary Sources) and the legal literature. The legal literature consists of monographs and contributions to the legal periodical literature as well as commentaries. The last are particularly important in civil law countries that follow or are close to the Germanic legal tradition. Commentaries are detailed annotations of each provision of a particular code, consisting of an analysis that brings together all case law dealing with this provision, opinions of others as expressed in the periodical literature, and the commentator's own evaluation and summary.

Case law by itself, as already mentioned in other contexts, does not have the same central importance in a civil law system as it does in a common law system. It is indeed a secondary source, for the judge is bound only by the enacted law, except in the few cases in which – as discussed before – the decisional law has reached the level of *jurisprudence constante*, or in systems in which a 'constitutional court' has power to bind other courts (e.g., Germany). To repeat, however, such cases are rare. Judges will read commentaries and the legal literature in general, just as lawyers do. The process of 'law finding' and its application, however, does not restrict the court to these sources.

Developing the Law

If 'law' is a norm in the form of a statutory codification or a 'general principle' derived from such statutory norms, how can a judge decide a case for which no norm or general principles exist, and, in the absence of legislative action, how can law develop further? (For comparative discussion see Adriaansen, 1998, p. 107; Hazard and Dondi, 2006)

Legislative action is of course the classic instrument for legal change. However, the process, from the drafting of a bill until its ultimate passage and entry into force, can be long. A commission for the revision of the German law of obligations, for instance, worked on this project for more than a decade. The final report of the commission was published in 1992. On January 1, 2002, the so-called Act on the Modernization of the Law of Obligations (*Gesetz zur Modernisierung des Schuldrechts*) came into force. The Act is considered the most important reform of the German Civil Code (*Bürgerliches Gesetzbuch* – BGB) since it came into effect in 1900. Thus, problems may need to be addressed that existing legal norms do not cover. The Swiss Civil Code is unique in its candid grant of discretion to the judge to fill the gap. It provides in Art. 1, §2: "if the Code does not furnish an applicable provision, the judge shall decide in accordance with customary law, and failing that, according to rule which he would establish as legislator." The assumption must be, of course, that even with such a grant of authority, the judge will try to fashion a result that conforms to the general structure and tradition of the legal system. The result will not contravene existing conceptions of what the law should be, but rather will fill the gap, and thereby contribute to the evolution of the law. One way of doing this is to work by analogy, that is, to compare the present problem with other problems that similarly require a weighing of the interests of the parties in the dispute. The analogy then extends the balance struck with respect to other problems of the present case. An example is the treatment of equipment leasing in German law. The German Civil Code contains provisions on leases and for sales (Section 535 et seq. for leases and Section 433 et seq. for sales), but not for leasing. Since leasing is regarded as possessing elements from both fields of law, case law and literature now derive rules from both and apply them to the phenomenon of leasing (even though in most cases the rules for leases are applied primarily, see Graf von Westphalen and Thüsing, 2012, Part 'Klauselwerke,' III, paras. 16–17, 24–26).

The Swiss provision just quoted confers discretion. However, it was suggested that no court will exercise unfettered discretion but will seek to follow the structure and implement the values of the particular legal system. This has also been the experience in other civil law legal systems, for instance, the German. The German Civil Code, as do others, contains provisions of great breadth and, consequently, lack of specificity. These are 'general clauses,' of which Section 242 of the German Civil Code is perhaps the best example. It requires parties to a contract to perform their obligations in 'good faith.' Section 242 has become the source of an extensive body of case law and of legal concepts not addressed specifically in the civil code. When the economic upheavals of the 1930s threatened parties to contracts with economic ruin, the German Supreme Court invoked § 242 to develop a doctrine of 'frustration of contract' (*Wegfall der Geschäftsgrundlage*) that permits courts in appropriate cases to adjust the obligations of the parties. Good faith, so the German court stated, requires the protection of both parties: Cancellation of the contract (by analogizing the situation to one of impossibility) would be unfair to one party; enforcing it in full (against the background of totally different and unexpected circumstances) would be similarly unfair to the other party. The French *Conseil d'Etat* – but not the *Cour de Cassation* – developed a similar remedy, the doctrine of *imprévision* (see Waline, 2010, paras. 452–455). It is interesting that a similar doctrine (and a remedy akin to the German) were never accepted to that extent in the United States despite the greater freedom of common law courts to fashion law through decisions and despite an express provision in the UCC imposing an obligation to deal in good faith (UCC Section 1–203).

The civil law doctrine of *culpa in contrahendo* furnishes another example. The obligations of parties to a contract begin with its conclusion, but expectations will have been created earlier, and their disappointment may cause damage. Such a situation could be dealt with under the law of *Delikt* (tort), but sometimes the preconditions for a remedy in tort will be lacking. Again, the extension of an existing provision may provide relief. Section 276 of the German Civil Code provides for liability for damage caused intentionally and negligently. For liability to arise, there must be some relationship, some duty owed to the other party. Such a relationship, the case law states, again invoking the parties' good faith obligation, is created by the contract negotiations. Parties thus have a precontractual duty of care to each other and may have a remedy for its breach. This is the doctrine of *culpa in contrahendo*. The common law again is less flexible; it generally does not impose contract law-based liability for precontractual misconduct; when it does not, a remedy must be sought in tort for negligent or intentional infliction of damage (Hay and Rasmussen-Bonne, 2011, p. 108).

The civilian judge, despite the different theoretical structure and focus of the legal system, thus can and does display the same creativity as do common law judges, with the principal – perhaps only – distinction that the decision in the individual case does not 'make law.' That new concepts can become part of the law, through repeated practice, is shown by the example just given.

At that point, while sources and methodology may differ, the practical result often no longer does.

The basic conceptual difference between common law and civil law finds reflection in still another area: the role of a judge and the conduct of a case. In common law jurisdictions, particularly the United States, litigation is 'fact driven.' The facts need to be established, and the applicable precedent must then be found. With such an emphasis on the facts of a case, the role of the lawyers is a particularly active one. The judge functions as a neutral arbiter; judges of courts of appeal ultimately decide questions of law (Hay, 2010, p. 90). In a civil law court, the judge starts with the rule of law, as outlined, and searches for the facts that he or she needs for the further categorization of the case. The judge's role thus is much more active. Facts are elicited by the judge; lay judges may participate as members of the court (particularly in commercial matters), but there is never a lay jury in private law matters. The judge also ascertains the applicable law, and, if the applicable rule happens to be one of foreign law because of the international aspect of the case, he or she may even have to ascertain the content of the foreign rule of law *ex officio*. As a result, decisions of civil law appellate courts will read quite differently from those of appellate courts of common law countries. Attention to factual detail will be very slight (this is particularly true of high French courts) and the emphasis will be on legal norms, rather than the other way round.

Legal Education and the Legal Profession

In the United States of the eighteenth and nineteenth centuries, a young person could become a lawyer by 'reading law in the chambers of a lawyer,' in other words by serving as a clerk. In the civil law countries of Continental Europe, legal education has been the monopoly of the universities for centuries. With 'doctrine' – not case law – the heart of the legal system, law faculties served as the only way of entry to the profession, and its faculty members equaled in stature the position of the high judges in common law systems (see Dawson, 1978). In earlier centuries, German appellate and supreme courts routinely sent case files to the prominent law faculties, virtually for final decision on doctrinal grounds. (For the practice of '*Aktenversendung*,' see Rheinstein, 1938, p. 7.) The influence of law professors on the development of legal doctrine thus has a long tradition and continues to this day. The course of study reflected, at least until recent times, both the strict categorization of the legal system into specific fields of law and the high level of abstraction that characterizes the deductive analytic method of the civil law. Practical training of the young lawyer was left to a period of time required to be spent in an official training program (such as the *Referendariat* in Germany) or as a junior lawyer under the direction of a licensed lawyer, combined with additional training (such as in France). Full admission to the practice of law then occurred with the completion of these additional requirements. The mindset of the young lawyer had been formed, of course, by the time the university studies were completed.

In more recent times, law curricula increasingly reflect the offering or requirement of election of interdisciplinary subjects. There is also increasing instruction in the use of new technologies, for instance, how to access and use legal databases. In addition, increased emphasis on international compatibility and equivalence of academic degrees has led to the introduction of baccalaureate programs in law (for instance, in Germany). The resulting bachelor's degree certifies academic study of law but is not the equivalent of the German *Referendar* for purposes of entry into the profession; additional study would be required for the latter. Neither increased 'skills training' nor the new degree programs affect the structure of the legal system.

Outlook

Civil law systems differ among themselves, as noted initially. This also holds true for the course of study and the practical training required to become a lawyer. As a result, a lawyer – as in the case of other professionals – may face impediments in attempting to establish a practice in another country or even to render occasional services there. In the European Union, the 1988 so-called Diploma Directive was one of the first steps to implement the European Community's freedom-of-establishment and free-supply-of-services provisions. The 1998 'Establishment Directive' requires foreign lawyers wanting to work permanently in another European Community country to pass an aptitude test or to have 3 years of practical experience in the state where they want to work. Today, requalification is governed by the 2005 'Recognition of Professional Qualifications Directive,' which replaced the 1988 'Diploma Directive.' In addition, the 2006 'Directive on Services in the Internal Market' also touches on the legal profession. The Council of Bars and Law Societies of the European Community is an organization that includes the national associations of lawyers of the member states of the European Union, the European Economic Area, and Switzerland. It has published the 'Charter of Core Principles of the European Legal Profession and Code of Conduct for European Lawyers.'

In the European Union, civil law meets common law in a shared organizational structure. Administrative regulatory action to facilitate the transborder practice of law has been accompanied by efforts to harmonize areas of private law. Legal scholars are documenting the doctrinal commonalities in various fields of law – under titles such as 'European-wide tort law' (see von Bar, 1996; van Dam, 2006; Koziol and Schulze, 2008), or 'Property law in Europe' (von Bar and Drobning 2004; van Erp et al., 2012) – and there has been discussion of the feasibility of a European Civil Code (see Kötz, 1996).

A number of efforts have borne fruit. In the European Union, the joining of many countries with a civil law tradition and two common law countries (the United Kingdom and Ireland), the 'Brussels I' and 'Brussels II' regulations provide common rules for jurisdiction and judgment recognition in civil and commercial matters and for divorce and child custody,

respectively, while the 'Rome I, II, and III' regulations provide uniform rules of private international law (conflict of laws) for contract, tort, and divorce. The first two of the Rome regulations apply in all EU countries, except Denmark, the third in a more limited number of countries. In 2011, the Commission of the European Union proposed a regulation on a 'Common European Sales Law' as an optional alternative to national law. The European Union thus serves as a laboratory for accommodating the civil law and common law systems. In 2012, effective in 2015, the Brussels Regulation was revised.

While there is, then, some movement toward a new *ius commune* in Europe – which, moreover, may ultimately extend to additional countries as a result of further enlargement of the European Union – many other civil law countries around the world will not participate directly in these developments. The 'new European law' not only seeks to bridge differences among the civil law countries and between them and the common law but may also be expected to effect reforms and innovations within the civil law generally. These may well serve as models for other civil law countries, for instance, for those in South America that grow together through similar processes of economic cooperation and integration.

Civil Liberties and Human Rights

Abstract

This article addresses the differences between civil liberties, civil rights, and human rights, approaching the subject from a multidisciplinary and global perspective. Among other aspects, the entry focuses on three fundamental tensions in this field: the tension between the philosophical origins of these concepts and their political and historical manifestations and influences; the tension between culture and universalism; and the ironic or ambivalent relationship between rights and state power. A concluding section discusses the special problem of terrorism and rights.

Civil liberties and human rights are the basic freedoms and claims individuals possess as members of political orders or as members of the human race. Civil liberties are essentially 'negative' political rights that stand as shields against state actions and infringements, whereas human rights may include (depending upon the theorist or political posture) these claims as well as broader claims to such things as social and economic rights, cultural rights, and collective rights of peace and environmental health. This article discusses the political and intellectual history of civil liberties and human rights, their contemporary domestic and international political and legal contexts, and major debates surrounding their usage. Emphasis is placed on the aspirations behind these concepts, as well as on the tensions and conflicts that accompany their use.

'Civil liberties' and 'human rights' are closely related terms that embrace the basic freedoms and claims to which individuals are entitled, either as citizens of a particular state or by virtue of being human. The very ideas of civil liberty and human rights presuppose two intertwined convictions: that individuals or groups in civil society have moral status independent of the organized power of society (e.g., the state); and that this power must respect the rights that flow from this status. Though they arose as a response to political and normative claims in the West, at the beginning of the twenty-first century civil liberties and human rights are at least officially endorsed by virtually all countries and the community of international law. The content and scope of these concepts are contested on philosophical and political grounds. Accordingly, the concepts provide a good method of examining the ways in which important philosophical and legal concepts interact with political and historical forces.

Basic Historical Background

The idea of a moral status independent of the state is tied in multifarious ways to notions of higher (or natural) or universal law, democracy, individual conscience, and limited government. These notions have echoes in history as far back as ancient Athens and Rome, and in medieval Christian thought. The modern turn toward individual 'rights' (as opposed to natural 'law') was the product of a complex historical process that included Renaissance and humanist emphases on human achievement and creativity; the Protestant Reformation's stress on individual religious conscience and religious pluralism; the Enlightenment's belief in the power of reason and the individual; the growth of markets; and – most importantly – the rise of democracy (*see* Law and Democracy). The specifically liberal tradition of limited government and natural rights arose in the political and intellectual history of several European countries, notably England, Scotland, France, and the Netherlands, and in the United States, in the seventeenth and eighteenth centuries.

Social contract theory in the seventeenth and eighteenth centuries envisioned 'social contracts' between the government and the citizenry based on the consent of the governed and the protection of natural rights. Building on the theory of Thomas Hobbes, John Locke (1998) maintained in his influential *Second Treatise on Government* (a work defending the Glorious Revolution in England in 1688, and the 1689 English Bill of Rights) that government's primary purpose is to protect the rights of individuals found in the state of nature, specifically rights to life, liberty, and property. The American Declaration of Independence (1776) and the French Declaration of Man and the Rights of Citizens (1789) carried these ideas further, declaring the primacy of civil and political liberties.

Basic Aspects of Civil Liberty and Human Rights

Definitions

Though the distinction between 'positive' and 'negative' rights (first articulated by philosopher Isaiah Berlin, 1969) is often blurred or overstated, civil 'liberties' are often considered negative rights in that they serve as shields that protect the liberty and rights of individuals and members of civil society from state oppression. They represent claims against state action. Classic civil liberties include freedom of speech, the press, assembly, and religion, due process and fairness in legal proceedings (especially criminal process), privacy, and freedom from illegitimate discrimination.

Civil liberties should be distinguished from civil rights. Civil 'rights' are often construed as more 'positive' rights, in that they entail the state bestowing a power to do something affirmative, or taking action to protect fundamental interests or claims against private (nongovernmental) actions. For example, the right to use privately owned public accommodations or

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86008-0

facilities, or the right not to be discriminated against in private employment, can be construed as civil rights. More broadly defined positive rights may include such claims as the right to a job, to obtain adequate housing, and to share in more equal distribution of resources. More aggressive state action is needed to effectuate such rights (*see* Civil Rights).

Civil liberties and rights are generally claims tied to citizenship in particular legal orders. 'Human rights' are more universal in nature; they exist simply because one is a human being. These include the civil liberties discussed previously, as well as freedom from torture, slavery, and degrading treatment; freedom of the family; and basic self-determination. Debate swirls around whether such rights include basic economic, social, and cultural rights and needs, or broader collective goods.

Though human rights claims can be derived from specific domestic or international legal sources, their claims are distinctively moral. As political theorist Jack Donnelley (1989) remarks, "Human rights claims are essentially extralegal; their principal aim is to challenge or change existing institutions, practices or norms, especially legal institutions." Accordingly, Donnelley emphasizes the 'possession paradox': Having a right is most important when "enjoyment of the object of the right is threatened or denied." Thus, human rights claims typically arise when a particular claim is not afforded legal protection by a particular country, such as same-sex sexual expression at one time in some states in the United States, or religious conscience in China today.
